Radiologic Laboratory Established—The establishment of a radiologic research laboratory as part of the cancer research program at Columbia University was announced on November 12. The effect of radiation on living cells will be the main concern of the new laboratory and, in connection with this the Florence Nightingale Hospital for cancer patients will be built by the city at One Hundred and Sixty-Third Street and Fort Washington Avenue near the Medical Center. Special attention will be given to treatment in which high voltage x-rays are used to destroy cancer; it was stated. A million volt therapy machine will be installed in Presbyterian Hospital and Sloane Hospital for Women in connection with the plan but priorities have delayed installation. Giordano Failla, Sc D, physicist at Memorial Hospital for the Treatment of Cancer and Allied Diseases, will direct the laboratory. His assistants will be Edith H. Quimby, A M, associate physicist at Memorial Hospital and Titus C. Evans, Ph D, research associate professor of radiology at the State University of Iowa College of Medicine, Iowa City.

Dr Crumline Honored—Dr Samuel J. Crumline for many years prominently active in the field of public health, was guest of honor at a dinner at the Waldorf-Astoria November 12 given by the Kansas Society of New York. Dr Crumline observed his eightieth birthday this year. Born in Eminton Pa., in 1862 Dr Crumline graduated at the Cincinnati College of Medicine and Surgery in 1889. He was a member of the Kansas State Board of Health from 1898 to 1904 and secretary from then until 1923. He was dean of the University of Kansas School of Medicine from 1911 to 1919. In 1914 he was president of the State and Provincial Health Authorities of North America. He joined the American Child Health Association in 1923 as director of states relations. From 1925 until the association was disbanded in 1935 Dr Crumline served as general executive. The speakers at the recent dinner included Charles P. Taft, LL D, assistant federal director, Defense, Health and Welfare Services, Washington, D C; Hon. Payne H. Ratner, Topeka, Kans., governor of Kansas; Osa H. Johnson, H. Clyde Holmes, president of the Kansas Society of New York; Lloyd Stratton, assistant general manager of the Associated Press; Hon. Henry J. Allen, Wichita, Kans., former governor of Kansas, who served as toastmaster, and Dr Crumline.

OREGON

Deaths at State Hospital Attributed to Poison—Forty-seven deaths occurred at the Oregon State Hospital, Salem and more than 450 inmates became ill after a meal in which scrambled eggs were served, November 18. Newspaper reports indicate that a patient who had been given storeroom keys "in violation of institution rules entered the wrong storeroom when sent for powdered milk and brought back six pounds of roach powder." The roach powder resembles powdered milk and the assistant cook admitted, it was stated, that he mixed it with the eggs without noticing the error. George A. Posen, an epileptic patient, admitted that he measured out roach powder by mistake when sent to the storeroom by the assistant cook. Credit was given to Mrs. Allie Wassel, aged 63, a kitchen attendant, for saving many lives by ordering all patients to quit eating after she herself had tasted the eggs and became violently ill. The institution has 2,800 patients, about 1,400 of them men.

PENNSYLVANIA

Portrait of Dr Pfahler—A portrait of Dr. George I. Pfahler, professor of radiology at the University of Pennsylvania School of Medicine, Philadelphia and since 1935 a member of the board of directors of Ursinus College, Collegeville, was unveiled during special services held to name the Hall of Science at Ursinus College in honor of Dr. Pfahler. The portrait was presented to the college by Mrs. Pfahler and is the work of Mr. Robert Susan. It now hangs in the foyer of the science building (THE JOURNAL, November 14, p. 853).

Philadelphia

The Packard Memorial Lecture—Dr. Martha M. Eliot, associate chief, Children's Bureau, U. S. Department of Labor, gave the Frederick A. Packard Memorial Lecture before the Philadelphia Pediatric Society, November 10. Her subject was "Children in Wartime."

Medical Club Celebrates Fiftieth Anniversary—The Medical Club of Philadelphia held a dinner meeting at the Union League, October 16 to observe the fiftieth anniversary of its founding. Dr. Walt P. Conaway, Atlantic City, N. J., presided and acted as toastmaster. Mr. C. William Duncan, a Washington correspondent and formerly associated with the now defunct *Evening Public Ledger* of Philadelphia, was the

guest speaker. Three hundred and twelve members and guests attended the dinner meeting, at which nominees were chosen for the elections to be held in January.

Dr Lewis Retires as Medical Director—Dr. Mary R. H. Lewis was guest of honor at a dinner, November 4, given by the staff of the Woman's Hospital to mark her retirement as medical director of the hospital. Dr. Lewis, who graduated at the Woman's Medical College of Pennsylvania in 1911, served her internship at the Woman's Hospital, Philadelphia, and has been connected with that hospital ever since as associate in obstetrics and later as chief of the department. For eleven years she was physician to women and lecturer in hygiene at Swarthmore College and in private practice in Swarthmore. Dr. Lewis was medical director of the West Philadelphia Hospital for Women from 1918 until it merged with the Woman's Hospital in 1929, when she became medical director of the new Woman's Hospital. Dr. Dorothy Donnelly-Wood was toastmistress at the dinner.

Tuberculosis Conference—A symposium on x-ray survey at the United States Navy Yard opened the annual Philadelphia Tuberculosis Conference, November 10, at the Ritz Carlton Hotel. The speakers were Dr. William Edward Chamberlain, Dr. David A. Cooper, Captain Earl C. Carr, senior medical officer, U. S. Navy, Dr. Horace R. Getz, and Commander Edward L. Bortz, M. C., U. S. Naval Reserve. Dr. George Morris Piersol presided. At the luncheon session presided over by Dr. Charles J. Hatfield, president of the Philadelphia Tuberculosis and Health Association, Dr. Hubley R. Owen, city director of health, discussed "Tuberculosis and Other Health Problems in England." The theme of the afternoon session, with Dr. William Harvey Perkins presiding, was "Tuberculosis and War," with the following speakers: Major General Charles R. Reynolds, M. C., U. S. Army, retired, Lieutenant Colonel Esmond R. Long, office of the Surgeon General, U. S. Army, Herman C. Hillebo, passed assistant surgeon, U. S. Public Health Service, Dr. Abraham J. Cohen, and Dr. Hubert W. Hethcington.

Pittsburgh

Meeting of Psychiatrists—The fourth annual dinner meeting of the Pennsylvania Psychiatric Society was held at the University Club on October 8. Col. Leonard G. Rowntree, M. C., A. U. S., Washington, D. C., chief, medical division, Selective Service System, spoke on "Selective Service and Psychiatry." An afternoon session at the Western State Psychiatric Hospital was addressed by Dr. William C. Sandy, Harrisburg, on "The State Bureau of Mental Health and the Problems Presented by the War," Dr. Grosvenor B. Pearson, "The Western State Psychiatric Hospital," and Dr. Herbert H. Herskovitz, Norristown, "Psychiatric Aspects of Service Men Transferred to the Norristown State Hospital."

TEXAS

Lectures on Mental Hygiene—The Hogg Foundation of the University of Texas, Austin, under the direction of Robert L. Sutherland, Ph.D., professor of sociology, has arranged a series of special lectures on mental hygiene at the University of Texas Medical Branch, Galveston, and at other medical centers through the state. Dr. Tom Alfred Williams, London, discussed war problems relating to traumatic neuroses and shell shock. A symposium was conducted during November by Drs. Emilio Mira, professor of psychiatry, University of Buenos Aires, Argentina, C. Charles Burlingame, Hartford, Conn., and Lieut. Col. Franklin G. Ebaugh, M. C., U. S. Army. In January Dr. Walter L. Treadway, medical director, U. S. Public Health Service, formerly chief of the division of mental hygiene of the service, will survey mass problems of mental hygiene during the war.

New Appointments in Cancer Project—The M. D. Anderson Foundation, Houston, which is financing with the state the development of the Texas State Cancer Hospital and Research Laboratories, has added to the staff of the new project J. K. Kline, Ph.D., and Fritz Schlenk, Ph.D., associate and assistant professor, respectively, of preventive medicine and public health at the University of Texas Medical Branch, Galveston. Dr. Kline worked with Robert Williams, D.Sc., on the synthesis of thiamine (vitamin B₁) and has recently been engaged in cancer research in Galveston. Dr. Schlenk was engaged in enzyme research in Stockholm before the war and has since been conducting nutritional studies relating to disease at Galveston. Collaboration is being arranged between the new cancer hospital in Houston and the institute of biochemistry at the University of Texas, Austin. A tumor clinic has been established at the John Sealy Hospital of the University of Texas, Galveston, to cooperate with the Houston institution.

WISCONSIN

Third Annual Dearholt Day—The third annual "Dearholt Day" was observed in Madison, November 17, under the auspices of the Wisconsin Anti-Tuberculosis Association, the University of Wisconsin Medical School and the Dane County Medical Society. Drs. Florence R. Sabin, Denver, formerly a member of the Rockefeller Institute for Medical Research, and David I. Smith, professor of bacteriology and associate professor of medicine, Duke University School of Medicine, Durham, N. C. were the speakers. Dr. Sabin discussed "The Functions of the Reticulo-Endothelial Cells" and "Cellular Reactions in Antibody Formation" and Dr. Smith gave two talks on "Diagnosis and Treatment of Certain Nontuberculous Infections of the Lungs Which Simulate Tuberculosis." The special observance is held in honor of the late Dr. Floyd C. Dearholt, Milwaukee, for many years executive secretary of the Wisconsin Anti-Tuberculosis Association. A similar program was held in Milwaukee November 16 in cooperation with Marquette University School of Medicine, Marquette, Marquette the Milwaukee Academy of Medicine and the tuberculosis division of the Milwaukee health department.

GENERAL

New Editor in Chief for Pathology Journal—Dr. Israel Davidsohn, Chicago, has been named editor-in-chief of the *American Journal of Clinical Pathology*, succeeding Dr. Robert A. Kilduff, Atlantic City, N. J., who has entered military service.

Survey of Plantations in Search for Cinchona Bark—As a part of the effort to conserve quinine, Norman Taylor, director of Cinchona Products Institute, Inc., New York is leaving soon for tropical America for a survey of plantations and sources of cinchona bark. The trip, which will include the region from southern Mexico to Bolivia has been authorized by the board of commissioners for the Netherlands East Indies and its purpose is a cooperative one in the war effort with governmental agencies and manufacturers so that adequate supplies of cinchona bark may be available.

New Tuberculosis Officers—Dr. Victor F. Cullen, State Sanatorium, Md., was elected president of the Southern Tuberculosis Conference at the annual meeting in Memphis, October 5-7. Logan H. McLean, Sanatorium, Miss., was chosen vice president and J. P. Kranz, Nashville, Tenn., secretary-treasurer. —Dr. Horton R. Casparis, Nashville (deceased), was elected president of the Southern Trudeau Society at its meeting in Memphis, Tenn., October 5-7. Other officers of the group are Drs. Duane M. Carr, Memphis, vice president and Julius L. Wilson, New Orleans, secretary-treasurer.

Annual Christmas Seal Sale—The thirty-sixth annual Christmas Seal Sale of the National Tuberculosis Association and its 1,700 affiliated associations throughout the country opened November 22. Eight million dollars has been set as the national total of the sale. Ninety-five per cent of the seal sale income remains in the state in which it is raised and 5 per cent of each state's return goes to support the work of the national association. As in all past years tuberculosis is on the increase, Dr. Kendall Emerson, managing director of the national association, stated in a release to the press. It has risen alarmingly in Europe and Asia he said, but so far in this country preliminary figures for 1942 indicate that tuberculosis deaths will be the lowest on record. He also stated that the full impact of the war on the campaign to control tuberculosis will probably be felt during the coming year. Dr. Emerson, in outlining the major activities of the tuberculosis association for the coming year, stressed medical research, the expansion of x-ray surveys among industrial workers, particularly young women, full assistance to men rejected from the armed forces because of tuberculosis, cooperation in the health program of the High School Victory Corps and a health education campaign to emphasize the need and ways of maintaining a high resistance to the disease.

Society News—Mr. Frank J. Walter, Denver was chosen president elect of the American Hospital Association at its recent annual meeting in St. Louis. Mr. James A. Hamilton, New Haven was installed as president, Dr. Harley A. Haynes, Ann Arbor, is the treasurer and Dr. Bert W. Caldwell, Chicago, is the executive secretary. The 1943 session will be held in Buffalo.—The American Medical Women's Association

will hold its annual midyear board meeting in Cincinnati December 5-6. Mrs. Oveta Culp Hobby, director of the Women's Army Auxiliary Corps will be the principal speaker at the banquet at the Netherland Plaza Hotel, December 5.—Dr. John Walker Moore, Louisville, Ky. was elected president of the Central Society for Clinical Research at its annual meeting in Chicago November 6-7, Dr. Cecil J. Watson, Minneapolis, vice president and Dr. Carl V. Moore, St. Louis secretary-treasurer.

Million Dollars Pledged for Diet Research—A fund of \$1,001,000 pledged to the Nutrition Foundation Inc. to support a five year program of basic research in the science of nutrition has been contributed by a group of food and related manufacturers. The announcement was made at a meeting of the foundation at the Chicago Club Chicago November 12. Eighteen additional grants-in-aid totaling \$46,000 were appropriated by the foundation's board of trustees making a total of fifty-four grants allocated this year to thirty three universities, colleges and medical centers. Among the universities receiving new grants are Northwestern Chicago, Illinois, Urbana-Champaign, Notre Dame South Bend Ind., and Wisconsin, Madison. Previous grants had been awarded to the Universities of Chicago, Illinois Minnesota, Purdue, Wayne, Wisconsin, Northwestern and the Children's Fund of Michigan, Detroit. Other institutions receiving grants at the foundation's meeting in Chicago include the Universities of Virginia, Arkansas, Stanford, Rochester, Southern California, Cornell and California and the Alabama Polytechnic Institute, Auburn. Harvard Medical School, Boston Mount Sinai Hospital, New York Postgraduate Medical School and Hospital, and the Memorial Hospital for the Treatment of Cancer and Allied Diseases. The new type of studies now being supported by the foundation include isolation of unstable food factors, protein utilization during partial starvation utilization and distribution of radioactive iron, protection of the teeth afforded by specific nutrients, liver synthesis of blood proteins, nutritive protection against infection, the relation of vitamin A to muscle metabolism, nutritive value of low cost vegetables, minimum vitamin needs of adults, metabolic balances in diabetes, nutritive protection of the blood vessels and the nutrient in cow's milk under specific conditions. It was announced also that the Safeway Stores, Inc., Oakland, Calif. and the American Sugar Refining Company, New York, had been elected as founder members of the foundation. The following have been elected sustaining members: Gerber Products Company, Fremont Mich., Golden State Company, Ltd., San Francisco, Chr. Hensen's Laboratory, Inc., Little Falls, N. Y., McCormick & Co., Baltimore, Minnesota Valley Canning Company, Le Sueur, Minn., and the Drackett Company, Cincinnati. The Great Atlantic & Pacific Tea Company also have made a substantial donation to the foundation. Mr. R. Douglas Stuart, Chicago trustee of the foundation presided at the meeting November 12. Charles G. King, Ph.D., New York, scientific director of the foundation presided at the afternoon program, the speakers at which included Icie G. M. Hoobler, Ph.D., Detroit, on "Explorations in Human Nutrition", Dr. Morris Fishbein, Editor of THE JOURNAL, "Medical Aspects of Our Food Supply", Col. Rohland A. Isker, Q. M. C., U. S. Army, "Nutrition and the Armed Forces," and Roy C. Newton, Ph.D., Chicago, "Fundamental Research in the Food Industry of Tomorrow." With Mr. George A. Sloan, New York, presiding, Sir John B. Orr, director of the Rowett Research Institute, Aberdeen, England and Karl T. Compton, LL.D., president Massachusetts Institute of Technology, Cambridge spoke at the dinner session.

CORRECTION

Examinations in Obstetrics and Gynecology—The American Board of Obstetrics and Gynecology announces that the next written examination and review of case histories (Part I) for all candidates will be held in various cities of the United States and Canada on February 13. THE JOURNAL, November 7 page 777 erroneously reported that this examination would be held in November. The Part II examination will be held in Pittsburgh, May 19-25.

Recommendations Concerning Venereal Disease—In the article by Dr. Otis L. Anderson and others concerning 'Recommendations to State and Local Health Departments for a Venereal Disease Control Program in Industry' in THE JOURNAL, November 14, on page 830 second column, under the heading "Employment Policy," item 3 should read "That, when syphilis exists in a latent stage, employment should not be delayed or interrupted."

(From Our Regular Correspondent)

Oct 24, 1942

Treatment of the "Compression Syndrome"

As reported in a previous letter (THE JOURNAL, June 28, 1941), the bombing of our civilian population from the air led to the discovery of a new pathologic condition—renal failure after crushing of the limbs by fallen debris. In a discussion at the Royal Society of Medicine it was suggested that the breakdown of autolytic products from dead or dying muscle seemed to be the main factor in damaging the kidneys. Not only were the cells of the tubules poisoned, but myohemoglobin was precipitated in the tubes. Among other measures early diuresis by means of abundant warm drinks was suggested as important. A quite different view of the pathology and treatment is now brought forward.

From the wards of the Middlesex Hospital and the attached Courtauld Institute Mr D H Patey, surgeon, and Dr J D Roberston, clinical chemical pathologist, bring forward the following view. On rescue the victim may look surprisingly well, but hours later he becomes gravely ill from shock, and, if this is overcome, within about twenty-four hours fresh anxiety arises from hematuria and low urinary output. Despite measures to promote diuresis, the oliguria increases to fatal anuria. The limb that has been pinned down becomes swollen and hard with edema and is partly or completely paralyzed by nerve compression. The writers object to the term "crush syndrome," for crushing and pulping of the tissues is not a striking feature. It is much more typical for the limb to show no evidence of damage except some cutaneous abrasions. A more accurate term would be "compression syndrome." The cause of the syndrome has given rise to much speculation. Most theories incline to the view that the syndrome is due to a toxin produced by the damaged tissues. But treatment based on this has been disappointing. In March 1941 the writers suggested that the cause of the syndrome was loss of blood constituents from the circulation into the tissues of the limb, the capillaries of which had lost their function in consequence of the long compression. But while unable to give a complete explanation of the renal phase they decided to introduce a new treatment based on their conception of the problem—restoring extravasated fluid to the circulation by intermittent pressure up to 60 mm of mercury applied to the limb by a specially made large blood pressure cuff firmly bandaged and connected with a passive vascular exercise motor. The advice to "apply a firm bandage" is not enough. Trials showed that with different types of bandage applied in different ways a wide variety of pressure readings were obtained, varying from ineffective to dangerous pressure. They use an elastic web bandage. How long the bandage should stay on will have to be determined by experience. At present it seems that it should remain for some days.

The writers have treated some cases successfully by this method. Strong experimental support is given by a paper by Duncan and Blalock in the April issue of the *Annals of Surgery*, who produced in dogs a similar syndrome. If the affected limbs were immediately placed in a pneumatic cuff with a pressure of 40 mm of mercury 75 per cent of the animals recovered, whereas in the control series the figure was only 5 per cent.

Anemia in Hospital Nurses on Wartime Diet

In connection with an article by Helen M M Mackay, R H Dobbs, Lucy Wills and Kathlin Bingham, which appeared in the *Lancet* July 11, showing the existence of low grade anemia in women and children on wartime diet, which is attributed to iron deficiency in the diet, Dr Helen P Wright

(*ibid*, August 1) has published a communication on this anemia in nurses. She made a survey of the hemoglobin of 100 day and 25 night nurses at a base hospital of the Emergency Medical Service and confirms the findings of Mackay and her colleagues. The average hemoglobin, estimated by the Haldane method, for the day nurses was 85.2 and for the night nurses 86 per cent. In the whole series 58 per cent had hemoglobin levels below the lower limit of normality (90 per cent), while of these over a fourth were below 80 per cent. The average age of the nurses examined was 23 years. The menstrual history revealed irregularity beyond the normal physiologic variation in 29 per cent, amenorrhea and menorrhagia were present in about equal numbers. Fourteen ward sisters, whose average age was 29, showed a higher average hemoglobin level than the nurses, their average was 91.4.

Dr Wright concludes that low grade anemia is common in the nursing profession at the present time. These young women work ten hours a day, often under trying circumstances. She agrees with the conclusion of the article as to the dietary nature of the anemia and the suggestions that iron fortified foods should be provided and that institutional diets should be under constant review in wartime. In the article referred to the deficiency of iron in the diet was connected with a low protein content, particularly animal protein. This is due to the war. It has been shown in previous letters to THE JOURNAL that the general health of the population is good in spite of restrictions, and this is still true. The anemia now described appears to be the first detrimental effect to be traced to the restrictions of rationing. But it should be remembered that some degree of anemia was not uncommon in women and children before the war.

Club for American Nurses in London

A club for American nurses has been opened in London. It will be the center for nurses who are in London on leave or are waiting to be posted. It will fulfill the same function as other clubs which have already been opened for the American fighting services and be a center of information and recreation. At the opening ceremony a broadcast was made to America by Mrs Biddle, who interviewed two of the nurses at the microphone, and by Mrs Churchill, who said "It is a rare opportunity for women of our two countries to get together and form such links of friendship and confidence as may endure from generation to generation." Captain Margaret E Aaron, superintendent of nurses in the European theater of operations, replied on behalf of the nurses. Mr W E Stevenson of the American Red Cross and Colonel Horley, Surgeon General of the American forces in this country, also spoke.

The club will eventually consist of seven houses in Charles Street. The first section, which was opened, contains the information bureau, sitting room, library, ball room, table tennis and card room, as well as dormitory space for fifty nurses. There is also a dining room to be opened soon as a restaurant serving meals on the cafeteria system and specializing in American dishes.

A Nutrition Council

A controversy is being waged in the *Times* by the leaders of the medical profession as to how the proposed Nutrition Council described in a previous letter, should be formed. Sir Charles Wilson, president of the Royal College of Physicians, thinks that it should not be a purely medical body and that it should be set up by the Food Investigation Board. Lord Dawson suggests that the Medical Research Council is a suitable body on which to base the new organization. Its duties are not exclusively concerned with medical research and its work overflows national boundaries. The latter point is important, as the Nutrition Council should direct the relief of the oppressed peoples of Europe when the Nazi scourge has been crushed. Of the Medical Research Council's varied staff of experts 60 per

cent have no medical qualifications. Its various committees cover a wide field besides medical research in the restricted sense. An investigation into the health of miners involved examinations of the men and their working environment and required the cooperation of mining experts, chemists and geologists. Its industrial health research board held an inquiry into the personal factor in accidents, for which a membership of eleven included experts on physiology, psychology, chemistry, health, vital statistics and two members of industrial experience.

In nutrition the work of the council is noteworthy. Sir Henry Dale, pharmacologist, who is president of the Royal Society, has until recently been director of the national institute at Hampstead, and his successor is a distinguished biochemist. From this institute have emerged many additions to our knowledge of nutrition and its applications. As far as concerns the empire, the council works in close cooperation with the dominions and the Colonial Office. Its staff has played a prominent part in the production of the "Report on Nutrition in the Colonial Empire." In the international sphere the council has done important work. One of its members was chairman of the International Technical Commission on Nutrition, which laid down the dietetic requirements according to age and work and is affected by pregnancy and lactation. Another example of team work was the International Committee on Vitamin Standardization, whose activities have been continuous since 1931. During the war two new vitamin standards, C and B₁, have been adopted. In the International Commission on the Relation of Nutrition, Health, Agriculture and Economic Policy the Council took a prominent part.

The Teaching at Guy's Hospital

The depletion by the war of the teaching staff of Guy's Hospital has created a problem. A prewar registrar of that famous hospital submits in a letter to *Guy's Hospital Gazette* that the fame of Guy's as a great teaching hospital has always been due in large measure to the noncramping methods employed. The Guy's student has always been taught to observe and come into close contact with patients and has been given the opportunity of studying and even treating cases himself to an extent unheard of in other hospitals. Formal teaching is reduced to a minimum, on the assumption that theoretical knowledge of clinical medicine and surgery can be obtained perfectly well from textbooks. The "cramming" system, practiced in some other medical schools, consists in numerous systematic lectures, demonstrations, teaching rounds, revision classes and so on, which leave little time for private clinical studies. While excellent for success in examinations, it does not fit a man nearly so well for the practice of medicine as does the Guy's system.

The prewar registrar states that shortly before the war more and more of the "cramming system" was being gradually introduced into the teaching methods of Guy's, for reasons which do not concern him at the moment. The effect on many students was unfortunate. They felt that they were having so much teaching that little or no effort was required on their part, and it became rarer and rarer to find students in the wards or outpatient departments when such attendance was required of them. Indeed, amid the welter of lectures, classes, teaching rounds and revision demonstrations they had little time to spare for private clinical work—that self teaching by constant personal contact with patients which is the essence of the Guy's teaching system. In addition, a feeling grew up that it was the duty of the medical school to get them through their final examinations, and they were both surprised and hurt when it was suggested that their failure to pass was due to their lack of initiative. At that time he and several of his colleagues on the junior staff deplored what was then only a tendency to the cramming system and felt that Guy's teaching was being jeopardized, though not to a serious extent. The students were

in danger of being overtaught. He suggests a reduction in the amount but not in the standard of teaching. Good teaching in clinical medicine should seek to guide and encourage the student to make his own observations and so develop his clinical sense and should never ape the textbook or degenerate into mere "spoon feeding." Such a method of teaching throws far more work and responsibility on the student, and the lazy man loathes it. But the keen and conscientious student finds that it well repays him in after years.

Oct 1, 1942

Transmission of Leprosy by Ticks

Dr H Souza Araujo of the Oswaldo Cruz Institute has carried out some experiments that have perhaps demonstrated that leprosy can be transmitted through the bite of common ticks. Starting from the fact published by Max Rudolf in *Brazil-Medico* (1918) that pupae of *Amblyomma cayennensis*, thirteen days after the last bite of patients affected with leprosy, showed live bacilli in the contents of the intestine, Araujo repeated the same experiments and ascertained that such bacilli seven days after the last bite, were poorly stained, vacuolated and perhaps in the course of digestion. After forty eight hours of feeding on patients with active leprosy the pupae of the same species of tick presented in more than 60 per cent of the specimens, homogeneous bacilli, well stained by the Ziehl-Neelsen method, forming bundles and small globi, with all the characteristics of *Mycobacterium leprae*. In a second note just published in the *Memorias* of the Oswaldo Cruz Institute Araujo describes his new experiments with a cattle tick *Boophilus microplus*. Several specimens of this tick were fed for a few days on active patients of the St Roque Leprosarium in the state of Parana and sent to Dr Araujo at the Oswaldo Cruz Institute. Seven days after the last blood meal the contents of the intestines of the ticks showed strongly positive acid fast bacilli. In the same note Dr Araujo describes the results of the cultures from the material of the intestines of the *Amblyomma* referred to in the first note. The cultures in Löwenstein medium are pure and the bacilli are strongly acid fast in a subculture. The culture material is not rich enough to make possible the inoculation in animals, which will be done in the near future.

Sterilization of Leprous Patients

Before the Sociedade Paulista de Leprologia, Drs Luis Batista and Luis Marino Bechelli discussed the sterilization of leprous patients. They presented the following conclusions:

- 1 Sterilization for eugenic purposes has no scientific foundation, for the infection is not transmitted by the germinative and congenital routes.

- 2 Sterilization with prophylactic intent presents so many difficulties that its application is impracticable. Besides this, it must be considered that the leprous male has a high index of sterility.

- 3 Sterilization has serious drawbacks, for it would cause great deprivation and dissemination of venereal diseases in leprous settlements and this menace would keep patients out of the leprosaries, making their entrance difficult, and so the prophylactic campaign against leprosy would be prejudiced.

Injections of Heat Killed BCG in Normal Children

Since several authors (Saye, Saenz, Sayago and others) have described human conditions closely related to the latent allergy of tuberculous guinea pigs (after Willis), an investigation has been conducted by A. De Assis in Rio de Janeiro to develop a standard technic for routine use in this field. Starting from the belief that the primary mobilization of the specific allergy depends rather on the chemical nature of the tubercle bacillus

than on its surviving capacity in the animal tissues, heat killed BCG bodies were used to arouse the tuberculin hypersensitivity of the organisms that could be considered in the state of latent allergy. In order to avoid any mistake regarding the specific character of the local and sensitizing effects of the bacillary bodies, 81 nontuberculous children were tested intradermally with 0.1 mg. of heat killed BCG (in 0.1 cc.) and kept thereafter under observation for some months. Since all the children were always living in nontuberculous environments and all of them failed to show any clinical or roentgenologic evidence of an eventual infection with virulent tubercle bacilli the reactions following the BCG inoculation could be correctly ascribed to the latter. The author has been able to register four different types of reactions: (a) 36 children remained practically unaffected by the BCG injection, showing only a slight noncaseous papule of 5 mm. diameter at the seat of the inoculum as long as their follow up lasted (one hundred and eight days), and none of these children became allergic; (b) 15 children failed to present any noticeable reaction around the inoculum but all of them reacted to intradermal tests with 2 mg. of old tuberculin (2 cases early in the second week); (c) 6 children presented lately (after the second week) caseous changes at the seat of their inoculum as well as a well defined local reaction but remained nonreactors; (d) 24 children showed both definite caseous local changes and a clearcut tuberculin hypersensitivity in 6 cases the latter appearing early in the second week. Therefore it is possible to conclude that: 1. The intradermal inoculation of heat killed BCG in nontuberculous children failed to produce tuberculin hypersensitivity in 51.9 per cent of the cases, while in the remainder positive tuberculin tests could eventually be found early in the course of the second week. 2. Caseous changes of the local BCG lesions may occur in about 37 per cent of the cases as the primary result of the introduction of dead bacterial bodies into the skin cells. These changes occur always after the second week and are quite different from the so called Koch's phenomenon in some cases being entirely different from the allergy changes, the latter seeming to be rather coincidental to them in all other instances.

Rural Tuberculosis in Brazil

The *Arquivos de Higiene* has published a contribution from Dr. Cesar Araujo on rural tuberculosis in the state of Bahia. Under the direction of Dr. Araujo of the Bahia State Department of Health an investigation is being carried out to ascertain the rate of infection and the rates of morbidity and mortality from tuberculosis, besides many details in connection with that rural population. Bahia lies entirely in the tropical zone of Brazil and has the highest percentage of Negro population as it was the center of African immigration during the sixteenth, seventeenth and eighteenth centuries. The Pirquet and Mantoux tests (1:100 and 1:10) are being used extensively, but the present contribution includes only the results of thirty-one rural areas where 7,351 persons have been tested. Of the thirty-one areas investigated, eight have a comparatively low mortality rate from tuberculosis (between 28 and 92 per hundred thousand of population), sixteen have a high mortality rate (between 114 and 199) and seven have a very high rate (between 201 and 352). This total of 7,351 persons is made up of 3,320 males and 4,031 females, 2,129 are white and 5,222 are Negro. As for the age groups, 1,466 were under 9 years, 2,673 from 10 to 19, 1,642 from 20 to 29, 817 from 30 to 39, 444 from 40 to 49 and 309 of 50 years and over. The total positivity of the Pirquet test, performed on all 7,351 persons, was 19.7 per cent, the Mantoux test 1:100, performed on 5,898 persons, was positive in 42.8 per cent, and the Mantoux 1:10, performed on 3,253 persons, was positive in 26.0 per cent. The infection rate, as expressed by the tuberculin tests, showed an average of 56.6 per cent for males and 65.6 for females, 59.3 per cent for white persons and 68.5 per cent for Negroes. As for age, there was

no significant difference between the two sexes within each age group, and the incidence of positivity was 40.3 per cent for 0-9 years, 65.4 per cent for 10-19 years, 77.4 per cent for 20-29 years, 78.9 per cent for 30-39 years, 78.3 per cent for 40-49 years and 73.2 per cent for 50 years and over. Within the groups of 0-9 and 10-19 years 20.8 per cent were positive in 134 infants below 1 year, 33.9 per cent in 560 preschool children and 55.1 per cent in 1,981 school children. To give a basis for comparison, it is interesting to point out that in the great cities like Rio de Janeiro and São Paulo the average positivity of the tuberculin tests is 9.5 per cent below 1 year, 18.7 per cent in the preschool age and 27.0 per cent in the school age. The total positivity rate varied in the thirty-one rural areas of the state of Bahia mainly in accordance with the different social groups apparently more correlated with the social and vocational differences than with the degree of rurality of the environment. The interior of Bahia, as the inland districts of the other northern states of Brazil, is being progressively infected with tuberculosis through the influence of the interhuman relations with the cities of the Atlantic littoral, the afflux of urban tuberculous patients in search of a drier and cooler climate, the low standard of living, the rural endemic diseases (hookworm disease, malaria), the lack of health education and deficient medical assistance.

Surgical Treatment of Varicocele

In a recent paper Dr. Eurico Branco Ribeiro, director of São Lucas Sanatorium in São Paulo, submitted a surgical method of treatment for painful varicoceles, with ptosis of the testis and glandular atrophy or in cases in which the disease may cause occupational disturbance. Dr. Ribeiro modified the method described by Zepherino do Amaral, which is widely employed by Brazilian surgeons.

The new technique is as follows:

1. The usual incision for inguinal hernia is made large enough to expose the aponeurosis of the external oblique, the spermatic cord and the external inguinal ring.
2. The spermatic cord is freed from the external ring to near the testis which is gently pulled from the scrotum.
3. Incision of the infundibuliform fascia and careful dissection of the spermatic vessels, from the vas deferens, are done.
4. The vas deferens is laid down, while the other elements of the spermatic cord—veins, arteries and nerves—are arched over the aponeurosis of the external oblique and here fixed by the plication of the same aponeurosis held in place by chromic catgut sutures. This results in a tunnel, which shelters the vessels and nerves of the spermatic cord, thus avoiding stasis of the blood.
5. The testis is kept in the right place by suturing the tunica vaginalis in the lowest part of the aponeurosis of the external oblique muscle. Another means of fixation is formation of the previously mentioned tunnel.
6. The skin is sutured.

Dr. Ribeiro stated that the first patients operated on by this method five years ago are in excellent condition.

Studies on Plasma

An experimental study on plasma by Drs. Carlos Schelim, Italo Martnari, Toledo de Carvalho and Paca de Azevedo in the Instituto Pnheiros of São Paulo was reported before the São Lucas Society recently. They reviewed the history of transfusion and pointed out the advantages of plasma over all the other blood substitutes. They reported a comparative study on blood and plasma in dogs submitted to hemorrhagic shock. They concluded that plasma quickly restores arterial pressure in dogs subjected to hemorrhagic shock. It is effective even when only 33 per cent of the quantity of the blood lost is employed. Plasma, they said, is an effective substitute for blood in cases of hemorrhagic shock.

Deaths

Luther Crouse Peter ♂ Philadelphia University of Pennsylvania Department of Medicine, Philadelphia, 1894, Medico-Chirurgical College of Philadelphia, 1896, emeritus professor of ophthalmology at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania, professor of ophthalmology at the Temple University School of Medicine from 1917 to 1930, specialist certified by the American Board of Ophthalmology, first president and formerly member of that board, member and past president of the American Academy of Ophthalmology and Otolaryngology, member of the International Congress of Ophthalmology and in 1922 secretary-treasurer member of the American Ophthalmological Society and the Association for Research in Ophthalmology, Inc., fellow of the American College of Surgeons, the Oxford (England) Congress of Ophthalmology, and the College of Physicians of Philadelphia consulting ophthalmologist to the Friends Hospital, Graduate Hospital of the University of Pennsylvania, the Memorial Hospital, Roxborough, and the Rush Hospital for Consumption and Allied Diseases, in 1934 received the honorary degree of doctor of science from the Susquehanna University, Schuylkill, Pa., and in 1938 the honorary degree of doctor of laws from Gettysburg (Pa.) College author of 'The Principles and Practice of Perimetry,' the fourth edition published in 1938 and 'The Extra Ocular Muscles' the third edition published in 1941, aged 73 died, November 12 in the Graduate Hospital of the University of Pennsylvania

David Sweeney Hillis ♂ Chicago, Northwestern University Medical School, Chicago 1898 professor of obstetrics at his alma mater specialist certified by the American Board of Obstetrics and Gynecology Inc., member of the Central Association of Obstetricians and Gynecologists fellow of the American College of Surgeons, past president of the Chicago Gynecological Society served as a lieutenant commander in the Medical Corps U S Naval Reserve, during World War I and was retired with the rank of captain was responsible for the development of the DeLee-Hillis stethoscope member of the advisory staff of the Chicago Memorial Hospital, chairman of the obstetrical department of the Cook County Hospital and attending obstetrician to the Passavant Memorial Hospital, where he died, November 9, of carcinoma of the lung aged 69

Edward Charles Fabre-Rajotte, San Francisco, McGill University Faculty of Medicine Montreal Que Canada 1899 member of the California Medical Association and the Pacific Coast Oto Ophthalmological Society member of the faculty of the University of Paris France, 1911-1912 served with the U S Volunteer Medical Service Corps in 1918, awarded the Chevalier of the Legion of Honor of France in 1935, chief surgeon of the eye, ear nose and throat department at the French Hospital, aged 67, died September 14

Henry B Marriott, Battlboro, N C University of Maryland School of Medicine, Baltimore, 1883 formerly served as mayor of Battlboro, member of the county board of commissioners and member of the county school board, member of the medical reserve corps of the U S Army during World War I, aged 79, died, October 24, of pneumonia

George Ainslie Hendry, Sydney, N S, Canada University of Toronto Faculty of Medicine, 1935 appointed a surgeon lieutenant in the Royal Canadian Naval Volunteers Reserve, May 20, 1941, aged 31, was lost at sea when his ship the *Ottawa* was torpedoed by an enemy submarine, September 13

David Jamieson, Durham Ont, Canada, University of Toronto Faculty of Medicine, 1878 formerly chairman of the Old Age Pensions Board, represented his constituency for twenty four years in the Ontario Legislature, four of them as speaker, aged 86, died, September 12

Edward Palestine Hawkins, Montrose, Minn., University of Michigan Department of Medicine and Surgery Ann Arbor, 1897 at one time physician in charge of the Montrose Hospital, aged 79, died, September 28, of coronary thrombosis

William Arrelous Page, Barlow, Ky, St Louis College of Physicians and Surgeons, 1903 member of the Kentucky State Medical Association aged 66 died, October 22, in the Illinois Central Hospital, Paducah, of cerebral hemorrhage

Otto Charles Sommerfield, Chicago College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1909, on the staff of the Belmont Community Hospital, aged 56, died, October 14, of coronary thrombosis

James P Oldham ♂ San Antonio, Texas, University of Louisville (Ky) Medical Department, 1886, past president of the Bexar County Medical Society, for many years on the staff of the Santa Rosa Hospital, aged 79, died, October 19

Charles Malone ♂ Boston, Tufts College Medical School, Boston, 1902, on the staff of the Forest Hills (Mass) Hospital recently on the courtesy staff and formerly on the regular staff of St Elizabeth's Hospital, aged 67, died October 10

Alfred Washington Westney ♂ Atlantic City N J, Hahnemann Medical College and Hospital of Philadelphia, 1897 on the staff of the Atlantic City Hospital aged 67, died, October 12, in Northfield of coronary occlusion

Frank Anthony Pagluca, Boston, Tufts College Medical School, Boston 1906, member of the Massachusetts Medical Society, aged 71, died, September 18 in the Boston City Hospital of cirrhosis of the liver and myocarditis

Louis Anthony Bontempo, Aliquippa, Pa Rush Medical College, Chicago, 1937, eye ear, nose and throat resident at the Lye and Ear Hospital Pittsburgh from 1937 to 1940, aged 31, died, October 9 of pulmonary tuberculosis

Paris T Carlisle, Frederica, Del., University of Pennsylvania Department of Medicine, Philadelphia, 1887, aged 78 died August 3, in the Pennsylvania Hospital, Philadelphia, of renal calculi and carcinoma of the bladder

James Monroe Matthews, Morrilton, Ark., Memphis (Tenn) Hospital Medical College, 1910, member of the Arkansas Medical Society, aged 66, died, September 25, of septicemia and lobar pneumonia

Albert L Bowman, Ottawa Hills, Ohio, Toledo Medical College, 1896 formerly served as coroner of Ottawa County aged 77 died, October 14, in Toledo of cardiovascular renal disease with cerebral hemorrhage

Oliver Benjamin Yarnell, Wenona, Ill., Keokuk (Iowa) Medical College College of Physicians and Surgeons, 1902 member of the Illinois State Medical Society, aged 65, died October 24, in Rochester Minn

Joseph Octave Ernest Prud'homme, Montreal, Que., Canada Laval University Medical Faculty Montreal, 1919 chairman of the hospital medical board of the Hotel Dieu aged 49, died September 2

Carl H Thomsen, Dolton, Ill., Northwestern University Medical School, Chicago 1900 aged 69 died, October 22, in St Luke's Hospital, Chicago, of peritonitis following an abdominal operation

John M Johnson ♂ Hartington Neb John A Creighton Medical College, Omaha, 1915, owner of St John's Hospital, aged 67, died October 17, in St Vincent's Hospital Sioux City, Iowa, of hemiplegia

Jefferson M Denby, Carter, Okla University of Nashville (Tenn) Medical Department, 1905 member of the Oklahoma State Medical Association, aged 65, died, August 22 in San Bernardino, Calif

Morrison Archibald Taylor, Estherville Iowa, State University of Iowa College of Homeopathic Medicine, Iowa City 1897, aged 84, died, October 17 in Liberty, Mo, of organic heart disease

Isaac Daniel Nolen, Newsite Ala Louisville (Ky) Medical College, 1892, member of the Medical Association of the State of Alabama aged 72, died, October 3, of cerebral hemorrhage

Jefferson Davis Walker, Denver, Kansas City (Mo) Medical College 1888, also a druggist, aged 81, died, October 10, in the Denver General Hospital of cerebral vascular accident

Daniel F Mooror, St George S C, Medical College of the State of South Carolina, Charleston 1874, aged 91, died, October 11, of arteriosclerosis, cerebral thrombosis and pneumonia

Bryan Lee Mitchell, Wilmette, Ill Rush Medical College, Chicago, 1926 served during World War I, on the staff of St Francis Hospital, Evanston, aged 45, died suddenly October 29

John Ferguson, Mount Forest, Ont, Canada, University of Toronto Faculty of Medicine, 1903, for many years medical health officer in Kincardine, aged 66, died suddenly, September 15

Oswald Edward Kennedy, Landis, Sask., Canada, Queen's University Faculty of Medicine, Kingston, Ont, 1916, aged 50, died suddenly, August 3, as the result of a fall in his office

Milton Harvey Evans, Joplin, Mo., University of Wooster Medical Department, Cleveland, 1890, Rush Medical College, Chicago, 1891, aged 81, died, October 6, of myocarditis

Robert Lee Cater, Perry, Ga., Jefferson Medical College of Philadelphia 1888, member of the Medical Association of Georgia, aged 76, died, September 16, of myocarditis

Benjamin Silas Potter, Artesia, Calif., Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906, aged 68, died, September 16, of heart disease

Henry Stanley Riddle, Camden, N. J., Medico-Chirurgical College of Philadelphia, 1904, recently a member of the draft board, aged 62, died, October 19, of heart disease

Nathan Joseph Cuden, Philadelphia, Jefferson Medical College of Philadelphia, 1933, aged 35, died, August 4, of pneumonia and hypertensive cardiovascular disease

Geza Bukki, Pittsburgh, Magyar Kiralyi Pazmany Petrus Tudomanyegyetem Orvosi Fakultasa, Budapest, Hungary, 1895, aged 71, died, August 11, of coronary occlusion

Olive B. C. McCurdy, Indianapolis Central College of Physicians and Surgeons Indianapolis, 1891, aged 75, died, September 21, in the Irvington Sanitarium

Jacques Conrad Saphier, Brooklyn, Cornell University Medical College, New York, 1940, diplomate of the National Board of Medical Examiners, formerly assistant resident at the Bellevue Hospital, New York, lieutenant (j g) U. S. Naval Reserve assigned to the Marine Corps, aged 27, was killed in action at Guadalcanal of the Solomon Islands, August 21

Robert Abraham Matland Cook, Calgary, Alta. Canada Trinity Medical College, Toronto, Ont. 1903 served overseas during World War I, aged 62, died, August 28

Harold Nelson O'Brien, Fullerton, Calif. Milwaukee Medical College, 1900, served during World War I, aged 65, died, September 28, of acute coronary occlusion

W. R. L. Dwyer, New Plymouth, Ohio, Medical College of Ohio, Cincinnati, 1883, aged 81, died, September 24, in the Athens (Ohio) State Hospital of arteriosclerosis

Jacob Hyman, Los Angeles, Ohio State University College of Medicine, Columbus, 1913, also a minister, aged 71, died, September 9, of carcinoma of the stomach

Judson Thomas Williams, Denver, Johns Hopkins University School of Medicine, Baltimore, 1919, aged 50, was found dead, September 25, of coronary occlusion

John Jamison Laird, Blackcreek, Wis., Rush Medical College, Chicago, 1904, aged 65, died, October 16, in Appleton of cerebral hemorrhage and diabetes mellitus

Norman John Claude Carter, Toronto, Ont., Canada, University of Toronto Faculty of Medicine, 1941, aged 33, died, October 8, in St. Michael's Hospital

John De Mott Ten Eyck, Franklin Park, N. J., College of Physicians and Surgeons, Baltimore, 1895, aged 76, died, October 10, of amyotrophic lateral sclerosis

Harry Robert Gourley, Pumasutawney, Pa., Ohio Medical University, Columbus, 1902, aged 70, died, October 20, in the Adrian Hospital of cerebral hemorrhage

Oliver Ringwalt Klugh, Harrisburg, Pa., Jefferson Medical College of Philadelphia, 1889, aged 75, died, September 14, of arteriosclerotic coronary artery disease

Lewis Hartley Lewis, Oshawa, Ont., Canada, University of Toronto Faculty of Medicine, 1928, member of the board of education, aged 41, died, September 25

Dennis J. Johnson, Seagrove, N. C., University of Tennessee Medical Department, Nashville, 1895, aged 73, died, September 4, probably of heart disease

Thomas Lea Brooks, Oceana, Va., University College of Medicine, Richmond, 1899, member of the Medical Society of Virginia, aged 65, died, August 21

Lionel Louis Albert, Yonkers, N. Y., Tufts College Medical School, Boston, 1912, aged 52, died, September 6, in the Yonkers Professional Hospital

Henry Carroll Conley, Boone, Iowa, University of Maryland School of Medicine, Baltimore, 1885, aged 80, died, September 26, of cerebral hemorrhage

Elbert Maltby Barnes, Gilman, Iowa, Northwestern University Medical School, Chicago, 1901, aged 67, died, September 9, of cerebral hemorrhage

Ephraim D. Rice, Flint, Mich., Detroit College of Medicine, 1894, member of the Michigan State Medical Society, aged 70, died, August 21, in Mio

Samuel Jesse Petty, Decatur, Texas, Fort Worth School of Medicine, Medical Department of Fort Worth University, 1901, aged 66, died, August 16

Emile S. Silbernagel, Vancouver, B. C., Canada, University of Pennsylvania Department of Medicine, Philadelphia, 1902, aged 64, died, October 16

George W. Cardwell, Elizabeth City, N. C., Leonard Medical School, Raleigh, 1899, aged 71, died, September 27, of carcinoma of the prostate

Newell E. Armstrong, Booneville, Ark., University of Arkansas School of Medicine, Little Rock, 1902, aged 74, died, September 15

Monroe Joseph Garrison, Chicago, Loyola University School of Medicine, Chicago, 1933, aged 33, died, September 17, in St. George's Hospital

Peter Christian Gilberson, Pasadena, Calif. Milwaukee Medical College, 1895, aged 78, died, October 6, of carcinoma of the small intestine

Charles Edward Kernodle, Elon College, N. C., University of Maryland School of Medicine, Baltimore, 1911, aged 63, died, October 15

Arthur Lewis Knisely, Brownington, Mo., Barnes Medical College, St. Louis, 1901, served during World War I, aged 69, died, October 12

Ladislaus M. Ottofy, Clayton, Mo., Homoeopathic Medical College of Missouri, St. Louis, 1888, aged 77, died, October 15, of heart disease

Leo Reich, Cleveland, Southern Medical College, Atlanta, Ga., 1895, aged 79, died, September 27, of coronary thrombosis and hypertension

Elmer Wellington Brown, Neustadt, Ont., Canada, Western University Faculty of Medicine, London, 1911, aged 57, died, August 20

David B. Craig, Attica, Kan., Eclectic Medical University, Kansas City, 1908, aged 84, died, October 26, of cerebral hemorrhage

Eugene Adolf Bergholz, Milwaukee, Rush Medical College, Chicago, 1934, aged 38, died, September 5, at his home in Wauwatosa, Wis.

William Thomas Gemmell, Stratford, Ont., Canada, Trinity Medical College, Toronto, 1903, aged 67, died, September 9

W. A. Crook, Michigan City, Ind. (licensed in Texas, under the Act of 1907), aged 67, died, October 7, of carcinoma of the larynx

John Peter Sinclair, Gananoque, Ont., Canada, University of Toronto Faculty of Medicine, 1894, aged 72, died, September 12

William L. Carroll, Struthers, Ohio, Baltimore Medical College, 1894, aged 77, died, September 22, of arteriosclerosis

John Baird, Superior, Wis., Trinity Medical College, Toronto, Ont., Canada, 1888, aged 82, died, October 3

James F. Blanchard, Creal Springs, Ill., Eclectic Medical Institute, Cincinnati, 1881, aged 86, died, September 26

James Wilson Fox, Brighton, N. Y., University of Buffalo School of Medicine, 1896, aged 76, died, September 22

Emile Dehaye Saint Cyr, Chicago, Rush Medical College, Chicago, 1888, aged 76, died, August 26

J. C. Frizzell, Bradford, Ark. (licensed in Arkansas in 1903), aged 67, died, October 10

J. Frank Parret, Levy, Ark. (licensed in Arkansas in 1903), aged 71, died, September 23

A REGISTRY OF OVARIAN TUMORS

To the Editor—At its recent annual meeting the American Gynecological Society undertook the sponsorship of an American Registry of Ovarian Tumors and appointed from its fellows a committee of five gynecologic pathologists to carry on this work.

The need and wisdom of such a project must be obvious to every gynecologist, for no problem of pathology is in greater need of clarification than this. No entirely satisfactory classification of ovarian tumors exists, largely because of our ignorance of the histogenesis of many of these growths. Even in tumor types which are fairly well defined, such as the papillary growths, prognosis is often difficult because of the not infrequent lack of parallelism between clinical and histologic malignancy, and mistakes in both diagnosis and prognosis are frequent. Again, tumors are not infrequently encountered concerning the nature of which even expert pathologists cannot be certain. Finally, a whole group of ovarian tumors of rather special histogenesis and microscopic appearance has been described in recent years, and there are many pathologists who, because of the relative rarity of these tumors, have had no opportunity of familiarizing themselves with their histologic characteristics.

Instead of limiting its study to a registry of rare ovarian tumors, comparable perhaps to that which has been employed so successfully by general pathologists with bone sarcoma, the committee has decided to widen its scope to include ovarian tumors of all varieties. It therefore seeks the cooperation of all gynecologists and pathologists in this ambitious project and appeals to them for cooperation by seeing to it that properly prepared slides of all ovarian tumors, more particularly those of unusual or doubtful nature, be sent to this central registry for composite study by the members of the committee.

With the slides should be sent an adequate clinical history, including such essential data as the patient's age, menstrual and marital history, gynecologic examination and the operative procedure carried out, as well as a gross description of the tumor. When photographs of the latter are available, they would be welcomed. If the gross specimen or blocks of tissue are sent, they should be fixed in 10 per cent solution of formaldehyde.

It is obvious that the real value of such a study would be enormously lessened if it did not include also a study of the subsequent course of the cases, particularly in the malignant and doubtful groups of tumors. Such correlated clinical and microscopic study must be the chief hope of improving our evaluation and classification of ovarian neoplasms. To facilitate such a follow-up study the name of the attending surgeon should be included in the data.

The committee has no intention of making this a purely diagnostic service, but all those who send in slides will in due course receive reports of the diagnosis and classification arrived at by the committee. Since each slide will be studied by every member of the committee and perhaps by other pathologists as well, and since this will involve correspondence between men scattered in different sections of the country, it will be understood that such reports of findings cannot be made with great promptness.

Finally, the committee fully appreciates that many of the ovarian tumors submitted to it will be worthy of report by the referring physicians, and it need scarcely emphasize that neither the committee as a whole nor any individual member will utilize any submitted case for publication without the express permission of the referring physician. It is hoped that, as the work progresses, reports of the committee's studies

will be published from time to time, but those referring cases for study will be given full credit in any such publication.

The committee feels that it has been given a great opportunity to render a worthwhile service, and it sincerely hopes that individual clinicians and pathologists in all sections of the country will feel that they too can contribute vitally in this project by developing the routine of sending slides of interesting ovarian tumors with the data indicated to the committee for study and registry. This material should be mailed to Dr. Emil Novak, Laboratory of Gynecological Pathology, Johns Hopkins Hospital, Baltimore.

FOOT BATHS FOR "ATHLETE'S FOOT"

To the Editor—In *Queries and Minor Notes* in *THE JOURNAL*, June 27, it was stated that "a satisfactory formula for a good powder for use in the treatment of trichophytosis is sodium thiosulfate 6 Gm and boric acid 24 Gm." I first described foot baths and this powder formula for this condition in *THE JOURNAL*, April 18, 1931, page 1301, and Oct. 3, 1931, page 1020. It is highly important to endeavor to eradicate as much as possible this most disabling of all foot infections. With this in mind I shall enumerate some of the advantages of both the powder and the bath.

1 *The Bath*. The sodium hyposulfite bath is stable. Chlorine, for example, is not. Chlorine too is an essential war chemical best used elsewhere.

My "hypo" bath can be made in any handy container—wood, metal, tile, in fact any material. The chlorine bath needs a rubber container. Many thousands of these rubber containers now being used for foot baths could be turned in for our war effort where rubber is so much more needed. Thus two war essentials, chlorine and rubber, could be salvaged.

The making of the "hypo" bath is not a procedure of chemical precision. Although I have recommended a 10 per cent "hypo" bath, I have also described that anywhere from 3 per cent up is effective. Even a very concentrated solution though not necessary, is harmless to the skin.

Ordinary "hypo" crystals, the large commercial type, in fact the "hypo" of photography, is the kind used for these baths. The crystals are much handier and more readily transportable than the unstable 0.5 or 1 per cent chlorine solutions. Many institutions have found success with the following crude but very practical method. Use any container large enough for the immersion of both feet. Add water to reach the level of the ankle. Throw a handful or cupful of "hypo" crystals into the water.

Where the "hypo" bath is near a chlorinated swimming pool, the chlorine content of the pool is not affected (*THE JOURNAL*, Oct. 3, 1931) particularly where an automatic chlorine content regulator is used.

2 *The Powder*. The powder may be in bulk or packaged in handy sifter top containers so as to be ready for use anywhere.

Solutions are good for the feet and floors only but not for the footwear. The powder is good for all three. The footwear, which harbors the trichophyton organism, is the common cause of infection as well as reinfection.

The powder need only be sprinkled lightly on the foot and footwear but more heavily on the floors of the showers and locker rooms. It is necessary to throw only a handful or cupful of this powder on the threshold leading from the showers to the lockers. By this simple expedient with the powder or, as before mentioned, by throwing a handful of the "hypo" crystals into the foot bath, we have effective means of combating this skin disease.

To be ideal, foot hygiene should be applicable and efficacious all the way from the home guard and the rear guard to the

front line trenches Keeping a soldier on his feet is paramount It is therefore of greatest importance that this most prevalent and most disabling of foot diseases be conquered That we have such simple means to do this under such varying conditions should be taken into consideration by all physicians caring for our civilians and fighting forces

Mississippi June Report

The Mississippi State Board of Health reports the written examination for medical licensure held at Jackson, June 24 25 1942 The examination covered 12 subjects and included 96 questions An average of 75 per cent was required to pass Forty-five candidates were examined, 43 of whom passed and 2 failed Twenty-two physicians were licensed to practice medicine by reciprocity The following schools were represented

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Foods Constitutionality of Municipal Ordinance Prohibiting Sale of Guaranteed Raw Milk—The Agricultural Code of California permits the sale of five grades of market milk, namely certified, guaranteed raw, guaranteed pasteurized, grade A raw, and grade A pasteurized. An ordinance was passed by the city and county of San Francisco authorizing the sale in the city and county of only four grades, namely certified, guaranteed pasteurized, grade A pasteurized and grade B pasteurized, thus proscribing the sale of guaranteed raw milk. The Natural Milk Producers Association of California, one of the plaintiffs, was a nonprofit cooperative corporation. It was not engaged in and did not intend to engage in, the production or sale of milk, although its members were engaged in that pursuit in California. The individual plaintiffs desired to sell guaranteed raw milk in San Francisco. Since such sales were prohibited by the ordinance, an action was instituted to enjoin its enforcement. From a judgment sustaining the validity of the ordinance, the plaintiffs appealed to the Supreme Court of California.

The plaintiffs first contended that since the ordinance prohibited the sale and distribution of two grades of milk that were approved by the state Agricultural Code, that is, guaranteed raw milk and grade A raw milk, the ordinance was in conflict with the state law and therefore invalid. Where the legislature has assumed to regulate a given course of conduct by prohibitory enactments, the court said, a municipal corporation with subordinate power to act in the matter may make such reasonable additional regulations in aid and furtherance of the purpose of the general law as seem appropriate to the necessities of the particular locality. The plaintiffs contended, however, that the Agricultural Code so completely occupied the field of regulation relating to the production, sale and distribution of milk for human consumption that there was no room for the operation of a local ordinance on the subject. With this contention the court could not agree, pointing to a provision in the section of the Code relating to milk that nothing in it was to be construed as "a limitation on the power of a municipality or county to provide for reasonable additional regulations not in conflict therewith requiring standards higher than the minimum requirements for the grades of market milk established in this division." The requirement in the ordinance that only pasteurized (certified excepted) milk could be sold was nothing more than an additional regulation, in the opinion of the court. The Agricultural Code permitted the sale of certified, guaranteed milk, both raw and pasteurized, and grade A, both raw and pasteurized. The ordinance merely imposed the additional restriction that the milk, whether it is guaranteed or grade A, must be pasteurized. The plaintiffs further contended that the ordinance was discriminatory in that it prohibited the sale of any milk other than pasteurized, with the single exception of certified milk, arguing that there was no substantial difference between guaranteed raw milk and certified milk. The court thought, however, that there was a substantial and reasonable difference directly related to the public health.

While the sale and distribution of milk, the court continued, is a lawful business protected by the Constitution, it cannot be doubted that its production, distribution and sale may be strictly regulated under the police power to safeguard the public health. That other less stringent or different regulations might have sufficed did not concern the court, as that was a matter lodged within the discretion of the legislative body.

The ordinance provided that "certified milk is market milk which conforms to the rules, regulations, methods and standards adopted by the American Association of Medical Milk Commissions and must bear the certificate of the Milk Commission of the San Francisco County Medical Society." The

court held that this provision did not constitute an unlawful delegation of legislative power. Such a provision, observed the court, is not essentially different from a statute requiring the applicants for a license to practice medicine to produce a diploma from a medical school whose requirements are in no particular less than those prescribed by the Association of American Medical Colleges, a private organization. There was evidence to the effect that in order for a producer to obtain a permit from the Milk Commission of the San Francisco County Medical Society authorizing the sale of certified milk in the city and county he was required to permit the commission to make an inspection of his facilities and the milk produced therein and to pay certain inspection fees which the commission had fixed to cover the cost of the inspection. The plaintiffs contended that this procedure was invalid because the Milk Commission of San Francisco County Medical Society was a nongovernmental body with no authority to collect fees or to issue permits. But, said the court, the ordinance contained no provision requiring the payment of fees or other charges to the Milk Commission or to any other nongovernmental body. No payment of a fee was demanded of the plaintiffs since they had not applied for a permit to sell certified milk in San Francisco. The authority of the Milk Commission to demand and collect inspection fees in connection with the certification of milk was therefore not involved in the case.

The judgment sustaining the constitutionality of the ordinance was affirmed.—*Natural Milk Producers Ass'n v. City and County of San Francisco*, 124 P. (2d) 25 (Calif., 1942).

Optometry Practice Acts Licensee Entitled to a Hearing De Novo on Appeal from Revocation Order—The California state board of optometry revoked the petitioner's certificate of registration to practice optometry, and he applied to the superior court for a writ of mandate to set aside the board's order, asking, among other things, that the superior court have a hearing and trial de novo. The court, however, considered only the record of the proceedings had before the board, denied the petitioner the right to introduce any new and material evidence and entered a judgment sustaining the board's order. The petitioner appealed to the district court of appeal which reversed the judgment of the superior court and subsequently denied the board's petition for a rehearing. (*Laine v. California State Board of Optometry*, 102 P. (2d) 538, J. A. M. A. 116 1738 [April 12] 1941.) The case then came before the Supreme Court of California on an appeal by the board.

The petitioner contended that he had a right to require the superior court to conduct a trial de novo in the course of which the parties would not be limited to the record made before the board. The Supreme Court pointed out that the state's governmental powers are divided into three separate departments—the legislative, executive and judicial. Under the state constitution the judicial power is vested "in the Senate sitting as a court of impeachment, in a Supreme Court, district courts of appeal, superior courts" and such inferior local courts as the legislature may establish. No other body may exercise statewide judicial power except as the result of constitutional amendment. If some agency with statewide jurisdiction other than the enumerated courts without sanction by constitutional amendment, exercises or attempts to exercise judicial power, such action is in direct violation of the constitution. The petitioner's right in this case to practice optometry was a vested property right. In the proceeding against him by the board all rights of "procedural" due process were accorded him. At the conclusion of the hearing an order was made revoking his license to practice. This would constitute an exercise of the complete judicial power contemplated by the framers of the constitution, and the petitioner would be deprived of his constitutional right, unless he had a right to go into a court of law and question the validity of that order by the introduction of any material evidence to prove that he did not commit the acts alleged.

The board contended, however, that by not providing for a court's hearing after determination by the board the legislature intended that the board's action should be final or at least that

a court should be confined to a consideration of the evidence produced at the hearing before the board. As evidence of the legislative intent in such matters, concluded the Supreme Court, reference need only be made to a recent act of the legislature proposing to voters of the state a constitutional amendment to give to the legislature the right "to confer power on administrative officers boards or commissions to make decisions." If the proposed amendment is adopted by the people, it will authorize the legislature to confer on such administrative bodies the right to exercise judicial power. Obviously, said the court, the legislature in proposing this constitutional amendment was of the opinion that it now has no such power.

The Supreme Court, therefore, held that the superior court erred in denying the petitioner the right to introduce material and competent evidence at the trial of this action and therefore reversed the judgment of the lower court—*Laine v State Board of Optometry* 123 P (2d) 457 (Colif, 1942).

Workmen's Compensation Acts Operation to Provide More Serviceable Stump Following Amputation of Foot—The claimant sustained an industrial accident to his right foot and the anterior part of the foot was amputated including all the bones beyond the ankle joint except the two bones of the foot and heel immediately below the joint, the operation being known as Chopart's amputation. The resulting stump healed without complications and the claimant was fully compensated under the workmen's compensation act for the loss of his foot. Difficulty was experienced, however, in wearing comfortably a prosthetic appliance and about three years later the claimant submitted to a second operation which resulted in the amputation of his leg at a point $7\frac{1}{2}$ inches (19 cm) below the knee. He then applied to the industrial commission for review of his case, contending that this second amputation was due to the industrial accident and that therefore he was entitled to compensation for the loss of part of his leg. Additional compensation was awarded, the district court sustained the award and the employer appealed to the Supreme Court of Iowa.

The court was unable to agree that the claimant was entitled to additional compensation. The only operation necessary for a complete recovery from the injury to the foot, said the court, was the first amputation, at which time there was no resulting infection and the stump entirely healed. At the time of the second operation, the claimant had lost a foot. This was the extent of his disability under the workmen's compensation act. Manifestly a second amputation was not necessary to the proper treatment of the foot. The injury to the foot did not require both operations. The sole purpose of the second operation was to give the claimant the maximum use of an artificial foot. It increased his capacity to labor and his earning power and reduced the economic handicap occasioned by the injury to his foot, and the Supreme Court, with three justices dissenting, felt that the claimant had received all the compensation to which he was entitled under the workmen's compensation act, that is, compensation for the loss of a foot. The award of additional compensation was therefore reversed—*Schell v Central Engineering Co*, 4 N W (2d) 399 (Iowa, 1942).

Drugs Misleading Advertising of Marmola a Violation of Federal Trade Commission Act—In 1929 the Federal Trade Commission, after hearings, found that the defendant company had used unfair methods of competition in selling a preparation called Marmola by making misleading and deceptive statements concerning its qualities as a remedy for overweight. A cease and desist order was vacated by the United States circuit court of appeals, 6th Cir., and by the United States Supreme Court (42 F (2d) 430, 283 U S 643, 51 S Ct 587), on the ground that there was no evidence that the defendant's product was in any real competition with other similar products in the interstate market. In 1935 the commission instituted the present proceedings against the same defendant and in connection with the same product, charging unfair methods of competition in violation of the Federal Trade Commission

Act. The commission found with particularity that the defendant had made many misleading and deceptive statements to further sales of Marmola, that Marmola had many active rivals for the trade of those who were interested in fat-reducing remedies, and that defendant's misleading statements had the "tendency and capacity" to induce people "to purchase and use respondent's [defendant's] preparation or medicine for reducing purposes in preference to and to the exclusion of the products of competitors, and to divert trade to respondent from such competitors engaged in the sale in interstate commerce of medicines, preparations, systems, methods, books of instruction, and other articles and means designed, intended and used for the purpose of reducing weight." The United States circuit court of appeals, 6th Cir., again vacated the cease and desist order (123 F (2d) 34), and the commission brought certiorari to the United States Supreme Court.

The findings of the commission were an adequate basis for its order, said the court. The evidence showed that sales of Marmola to the consuming public were made at retail drug-stores through the country, that defendant distributed Marmola both to wholesalers and retailers, that the wholesalers and retailers who sold Marmola also sold numerous other remedies for taking off fat, that the essential fat reducing element in Marmola is desiccated thyroid, which is also an element in some of the other remedies sold to the public with or without doctors' prescriptions, that many books of instruction on methods of reducing weight were sold in interstate commerce, and that the gross sales of Marmola were from \$350,000 to \$400,000 a year. From this and other evidence the commission concluded that numerous antifat remedies were offered for sale in the same market as Marmola and that Marmola was in active competition with them for the favor of the remedy purchasing public. It is not necessary, said the Supreme Court, that the evidence show specifically that losses to any particular trader or traders arise from the defendant's success in capturing part of the market. One of the objects of the act creating the Federal Trade Commission was to prevent potential injury by stopping unfair methods of competition in their incipency. And, the court continued, when the commission found as it did here that misleading and deceptive statements were made with reference to the quality of merchandise in active competition with other merchandise it was also authorized to infer that trade would be diverted from competitors who do not engage in such methods.

The judgment of the circuit court of appeals was reversed with directions that the order of the Federal Trade Commission be affirmed—*Federal Trade Commission v Marmola Co*, 62 S Ct 966 (1942).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Apparent Cure of Periarthritis Nodosa with Sulfapyridine. Report of Case. B. A. Goldman, K. L. Dickens and J. R. Schenken, New Orleans.—p. 443.

Acute Bacterial Endocarditis of Tricuspid Valve.—An incidence of 25 per cent or 646 cases of acute bacterial endocarditis was found by Goldburgh and his co-workers among 26,007 necropsy records at the Philadelphia General Hospital. In only 20 of these was the tricuspid valve alone involved. If the cases in which the tricuspid and pulmonary valves were affected in association with left-sided endocarditis are included, vegetations in the right chambers of the heart were present in 53 cases. The condition in 9 of the 20 was due to the pneumococcus, making it appear that the pneumococcus attacks the tricuspid valve more frequently than other organisms. If the cases of pneumococcal endocarditis are separated from the group as a whole, 9 of 62 cases of pneumococcal endocarditis, or 14.5 per cent, occurred on the tricuspid valve alone, but only 11 of 584 (1.8 per cent of all other cases of acute bacterial endocarditis) were restricted to the tricuspid valve. The findings on auscultation are apparently unreliable, as in only 8 of the 20 was it mentioned that any murmur was heard and in none of these was it heard specifically over the tricuspid area. Vegetations

may be large without producing cardiac murmurs. The absence of auscultatory changes should not eliminate a diagnosis of bacterial endocarditis. The continuance of a positive blood culture in pneumonia longer than a week should cause one to suspect acute bacterial endocarditis.

Bacterial Endocarditis in Congenital Heart Disease.—The incidence of acute and subacute bacterial endocarditis and endarteritis in hearts with congenital defects is discussed by Gelfman and Levine as they found it from the collected data of four large hospitals in Boston. Congenital cardiac defects were present in 133 per cent or in 453 of 34,023 necropsies, but only 0.5 per cent were of persons more than 2 years of age (181 cases). The incidence of superimposed bacterial endocarditis and endarteritis was 6.6 per cent in the whole group and 16.6 per cent in the group more than 2 years of age. The distribution of males and females was in a proportion of 3 to 2 in both the total group with cardiac defects and in those who showed infectious endocarditis. Sixty per cent of the patients died before the age of 2 years and for the rest there was no predominance in any one age group. The highest incidence of bacterial endocarditis was in the second and third decades. In 25 of the 181 more than 2 years of age with congenital cardiac defects there was the further complication of rheumatic infection. Congenital bicuspid aortic valve and interauricular septal defects were the most frequent underlying cardiac anomalies, and subacute bacterial endocarditis was present in 8 of the 25. The incidence of bacterial endocarditis for interauricular septal defects for the group was none for interventricular septal defects 42 per cent, for patent ductus arteriosus 28.6 per cent, for bicuspid valves 17.4 per cent, for the tetralogy of Fallot 12.5 per cent and for pulmonary stenosis 19 per cent. The respective figures for patients more than 2 years of age was also none, 57, 20, 21, 29 and 29.

Therapy in Sprue Syndrome.—Hanes reports 4 cases in which, though the most stringent diagnostic requirements of the sprue syndrome were fulfilled, there was poor or no response to adequate liver and dietary therapy. It is frequently impossible to establish the diagnosis of sprue without a quantitative estimation of the fats in the stool. The differential possibilities to be considered in its diagnosis are pernicious anemia, multiple avitaminoses, pancreatic disease, tabes mesenterica, gastrocolic fistula, anorexia nervosa and Simmonds' disease. The sprue in the 4 cases was decidedly refractory to the usual form of therapy. Under certain conditions the morbid process appears to be irreversible. The reason for such occasional refractoriness is not known. Three of the 4 patients died, and the necropsy of 2 revealed changes similar in every way to those reported by other observers, that is extreme inanition which was inadequate to explain the fatal outcome.

Primary Coccidioidomycosis.—Winn and Johnson observed the roentgen pulmonary features in 40 cases of primary coccidioidomycosis from the clinical illness and until they cleared remained stable or progressed. Depending on the amount of

infection a small nodular area of opacity may be all that is visible or, on the other hand, there may be single or confluent areas of pneumonitis in the pulmonary bases. In many instances the lesions appear predominantly exudative and clear rapidly. Occasionally a little residual fibrosis may remain. There is a tendency for pulmonary foci of primary coccidioid infection to appear like productive lesions and then to clear and decrease in size slowly and incompletely, leaving nodular densities suggesting caseation that eventually may calcify. Calcified pulmonary lesions in children with positive cutaneous reactions to coccidioidin and negative reactions to old tuberculin and to purified protein derivative are evidences of previous coccidioid infection. The cavity formation that accompanies the early acute phase, usually single, may close spontaneously or it may persist despite regression of the other pulmonary lesions. It then becomes thin walled and cystlike in appearance with little or no surrounding collateral reaction and changes little in size, shape or appearance in several years. Although these cavities serve as reservoirs for the existence and growth of *Coccidioides immitis* they apparently cause no injury to the health of the person. They are frequently the source of small repeated hemoptysis which is the only factor leading to their detection. Localized bronchiectasis may also result from coccidioid infection. Initial infection is sometimes manifested by a primary pleuritic effusion with *Coccidioides immitis* in the fluid. Secondary mediastinal or hilar adenopathy in primary coccidioid infection is infrequent but, when visible, has preceded fatal dissemination of the disease. Primary coccidioidomycosis is seldom a progressive disease, but if it is acute or chronic in its dissemination. Distribution suggests systemic seeding via the blood stream, with entry from involved lymph nodes. Hence the seriousness of advancing adenopathy following the initial infection. Acute disseminating primary coccidioidomycosis is probably always fatal in five weeks to seven months. Chronic disseminating coccidioidomycosis (coccidioid granuloma) has a mortality of 50 to 60 per cent. The coming of many uninfected persons, especially military personnel, into inland California valleys and certain parts of Arizona and Texas will result in a proportionate increase in the incidence of coccidioid infection.

Etiology and Serum Treatment of Encephalitis.—In their study of the etiology of encephalitis as it occurred in the summer and autumn of 1941, Rosenow and Caldwell noticed that the manner of spread and the incidence of the disease were strikingly like those in epidemic poliomyelitis. Definitely a specific encephalitis type of streptococcus was isolated from the nasopharynx, stools, brain and spinal fluid of patients and from the brain of horses and other animals having encephalitis or which had died from it. The streptococcus was agglutinated specifically by human and equine antistreptococcus serums by the equine encephalomyelitis antiviral serum (western type) and by serum of patients convalescing from encephalitis. The presence of this particular streptococcus among ill persons and animals and in well "contacts" and "noncontacts" and in outdoor air in the epidemic zone is of great epidemiologic importance suggesting that the disease may be air borne. Only patients for whom a diagnosis could be made definitely by means of spinal puncture or the classic signs and symptoms of the disease received serum treatment. The results are strikingly favorable, especially when treatment was started early in the course of the disease. The effect of serum was most striking in relieving the distressing headache (within a few hours) and nausea and vomiting than the effect on the duration of fever (about six and a half days). At first patients received 10 or 20 cc of serum intramuscularly once or twice a day. Later, because of the frequent return of cutaneous tests to positive the dose was 5 cc at intervals of four hours. A secondary increase in temperature was prevented in this manner. Not infrequently a secondary increase in temperature appeared when serum therapy was stopped, and for this reason the authors recommend that treatment with serum be continued for at least one day after the temperature has returned to normal. An occasional temporary increase in temperature occurred as an immediate reaction. Hives usually developed as a late reaction.

Toxic Eruptions Due to Phenobarbital.—Two cases of severe toxic eruption following the use of phenobarbital are reported by Moss and Long. Both patients recovered. In addition to the skin, all the mucosal surfaces, except the bronchial and urinary systems, were obviously affected. No loss of hair occurred, but each patient eventually shed all finger and toe nails. One of the patients took 1.53 Gm of phenobarbital in twenty days and the other 4.8 Gm in thirty-nine days. The authors suggest that phenobarbital intoxication may well have been the causative agent in many cases recorded in the literature as "atypical erythema exudativum multiforme" of unknown cause. They say that the cutaneous and mucosal eruptions of these cases resembled closely those of their 2 patients.

Cortical Representation of Macula Lutea.—Putnam and Liebman review the origin and development of the conception of the cortical representation of the macula, especially of bilateral representation of both halves of the macula, and evaluate the available data. The preponderance of evidence favors extremely large representation of central vision at the posterior end and in the depths of the calcarine fissure. Central vision may have some representation even at the anterior end of the fissure and, if it does, it is doubtless in the portion adjacent to the ventricle. There is considerable evidence that a callosal bundle uniting one geniculate body with the striate cortex of the opposite side does not exist. Many cases are recorded in which a homonymous hemimacular scotoma existed, but the lesion in the only brain examined was found at the tip of the occipital lobe. Usually the lesion has been traumatic and presumably injured the optic radiation. Unilateral lesions of the anterior portion of the striate area produce a contralateral hemianopsia with a large remnant of central vision. Lesions of the tip of the occipital pole produce a hemianopsia with irreg

ular homochries, sometimes with only 1 or 2 degrees of central vision. Neither type of central field is actually "macular." Total or subtotal lesions of one occipital lobe may produce either a complete hemianopia or one with varying traces of central vision. The persistence of central vision when a lesion of the occipital lobe exists may be due to extensive representation of macular vision. Another explanation for a tiny remnant of central vision is that there is a constant physiologic shift of fixation. In some cases a new fixation point is formed within the preserved field. Finally a certain degree of visual perception may be taken over by lower centers after occipital lesions.

Pits in Optic Disk—Greer reviews 69 cases of congenital deformity, pit or crater like depression, of the optic disk reported in the literature since 1882, when Wiethe cited the first case, and 3 cases of his own. Central field changes were present in the 3 and also peripheral field changes in 1. These pits or crater like holes of the disk should be classified as atypical colobomas. In all cases studied pathologically, pigment epithelium has been present in the pit or hole. No further explanation appears necessary for the ophthalmoscopic appearance of the excavation.

Carcinoma of Prostate—Evans and his associates determined the effect the grade of 100 consecutive cases of carcinoma of the prostate, studied between 1925 and 1936 and followed until death or for at least five years, had on life expectancy. Necropsy was done in 25, while 9 patients are still living. Study of the average survival time shows a decided decrease as the malignant grade of the carcinoma increases when grading was based on acinous structure, cell structure and nuclei. The same relationship was noted with the composite grade, so that a survival time of five and four tenths years in grades 1 and 2 (combined) decreases to two and two tenths years in grade 4. The percentage incidence of metastasis was 20, 29 and 44 in composite grades 1-2, 3 and 4, respectively. The higher grades of carcinoma occurred at slightly earlier ages than the lower. Roentgen therapy appeared to lengthen the survival time, especially of patients with the higher grades of carcinoma.

Two Point Coagulation Follow Up: Report on New Technique and Instrument for Electrocoagulation in Neurosurgery. J. Greenwood Jr. Houston, Texas—p. 552.

Artificial Fever Therapy for Neurosyphilis—Since 1931 Kendall and his associates have subjected 1,376 neurosyphilitic patients to artificial fever therapy and chemotherapy. During the first six years the usual course of treatment consisted of ten weekly five hour sessions of artificial fever at 105 to 106 F. After the combined fever and chemotherapy was completed the patients received twenty weekly injections of bismuth and arsenic preparations. During the last five years the fever therapy was reduced to twelve three hour sessions, and many patients were treated two and three times a week. These more frequent sessions have proved advantageous, particularly since the advent of hospital insurance, as the patient can be admitted for thirty days and receive a full course of treatment. Only 271 neurosyphilitic patients observed for not less than eighteen months are considered in the report. The records of 64 are excluded

because of incomplete post-therapy observation. The records of the remaining 208 show that the remission rate was 52 per cent and that an additional 28 per cent were improved. Thus a total of 80 per cent of the patients were benefited. The successful results are sufficiently comparable to justify the categorical statement that artificial fever therapy is at least as effective as malaria therapy in the management of symptomatic or asymptomatic neurosyphilis. Many reliable investigators have obtained significantly superior results with artificial fever therapy; patients tolerate artificial fever therapy better, the treatment can be carried out on an ambulatory basis without interrupting employment, and complications are minimized. The concurrent use of chemotherapy and artificial fever increases the therapeutic effectiveness of both agencies.

Ultraviolet Blood Irradiation—Miley injected into 71 patients with peritonitis blood that was irradiated with ultraviolet. Of 39 with generalized peritonitis 32 recovered. 100 per cent of those with moderately advanced peritonitis and 53 per cent of those who were apparently moribund. Signs of early detoxification appeared within an average of thirty-four and five tenths hours after initial irradiation, the average complete detoxification time was eighty-one and three-fourths hours. Twenty-nine patients received one, 6 two and 4 more than two treatments. Ultraviolet blood irradiation was used to control infection of 20 with localized peritonitis and appendical abscess, 17 recovered. 100 per cent of those with moderately advanced infection and 75 per cent of the apparently moribund. The average early detoxification was apparent in twenty-four and seventy-one hundredths hours and complete detoxification in fifty-two and ninety-four hundredths hours. Fifteen patients had one irradiation, 4 two and 1 more than two. Of the 12 patients with severe pelvic peritonitis accompanied by multiple pelvic abscesses 9 recovered, the 3 in whom the peritonitis was moderately advanced and 67 per cent of those who were moribund. Detoxification was apparent in fifty-four hours, complete detoxification occurred in 10 patients at an average of ninety hours. Five patients received one, 6 two and 1 three irradiations. There were 14 deaths, all occurred among the 33 apparently moribund patients.

Tuberculosis in the Canadian Army—A survey by Warner shows that 3,987 men, or 1 per cent were rejected at the time of enlistment for pulmonary tuberculosis and of tuberculosis developing in the Canadian army from September 1939 until March 1942. These men had considered themselves physically fit to join the army. The extent and character of the disease in these men was pleurisy in 73, minimal tuberculosis in 1,970, moderately advanced disease in 1,298, far advanced in 262, 179 with calcified lesions and 196 with supposed tuberculosis. Those with minimal, moderately advanced and far advanced disease had active or potentially active tuberculosis. Only 270 of the minimal cases could be diagnosed on clinical

findings when the lesion had been shown on the roentgenogram. Of the moderately advanced cases 357 could be diagnosed clinically and of the far advanced cases 117. In the series 293 presented a cavity and were obviously open cases. In 48 the tuberculosis could not have been diagnosed or suspected by clinical means. Only 114 men were returned from overseas with clinical tuberculosis which developed in the army from September 1939 to March 1942. The physical status of 10 of them at the time of admission was not up to par and they were enlisted by error. Ninety-six of the 104 were admitted with negative roentgenograms and clinical examination, while 8 showed small apparently healed lesions on admission but were considered fit for service. The 8 must represent a small percentage of those enlisted with small healed lesions. The policy of enlisting such men appears sound and will be continued. The average duration of symptoms in the 104 until the diagnosis of pulmonary tuberculosis was two and seven-tenths months.

Post-Traumatic Headache and Dizziness—The treatment in 92 consecutive cases of post-traumatic headache and dizziness was assessed by Lehmann and Elvidge to determine, if possible, what factors were responsible for their development. The cases represent one hundred accidents, 2 patients were hurt on three different occasions and 4 on two occasions. The patients, and when necessary the attending physician and the hospital in which treatment was received were questioned by letter concerning the original treatment received. The 92 patients were admitted to the Montreal Neurological Institute for post-traumatic headache between 1934 and 1940 inclusive. Investigation revealed that 18 had suffered linear fractures of the vault, 2 fractures of the base and 8 minor depressed fractures, in 73 the injury produced no evidence of fracture. There was an immediate loss of consciousness or lapse of memory at the time of the initial injury only after sixty-five of the one hundred injuries. Only 6 had evidence of a cerebral contusion with blood in the cerebrospinal fluid or seizures following the injury. As none of the patients had leaks of cerebrospinal fluid this may simply be further evidence of the moderate nature of the injuries or, conversely, a leak of spinal fluid in severe injuries may tend to prevent or to minimize post-traumatic headache. Its effect may be similar to that of lumbar puncture—the production of a natural decompression. That this happens is frequently obvious in clinical experience. The headaches were of two types: a dull, heavy, pulsating ache, a sense of pressure, fullness or tightness of the head which may or may not be throbbing in character but is interpreted by the patient as deep seated, and a sharp shooting, stabbing, sticking, lancinating, focal pain, usually felt at the site of injury with some radiation. The first type occasionally and the second type frequently is accentuated or influenced by change of posture of the head or head movements. Both types are usually accentuated by excitement, fatigue, mental effort, exertion, changes in the weather and occasionally imbibition of alcohol. The majority of headaches fell into the second group, but many were of both types. Sixty-nine patients complained of dizziness usually induced by stooping and generally independent of headache. Of the 70 patients on whom accurate follow-up data were obtained only 9 had had a lumbar puncture within three days of the accident, while 61 had had none at all. Only 31 were treated in a hospital, while only 47 had had adequate bed rest for their particular injury, 11 had had less than seven to ten days of complete bed rest and 18 had had no bed rest. The few patients who had lumbar puncture were among those who had had adequate bed rest. Fifty-eight of the 92 patients received spinal insufflation of air or air injected under pressure into the subdural space through a trepanation at the site of maximal pain, 28 were definitely improved, 9 moderately improved, 7 unimproved and 14 were said to be improved at the time of discharge but no further follow-up information is available. It is the authors' conclusion that usually patients who come with post-traumatic headache have been poorly treated from the start.

Chronic Chlorosis as Operation Hazard—To obtain an analysis of the surgical risk, complications encountered and the treatment necessary to improve the results in "chlorotic" patients, Abbott and Adamson studied one major more or less standardized surgical procedure. The treatment of 300 cases for uterine fibroids so often associated with menorrhagia and

secondary anemia and requiring some form of hysterectomy, was chosen for investigation. In 244 the hemoglobin estimation was 65 per cent or more on admission and in 56 it was below this and had to be corrected before operation. A total hysterectomy was performed in 67 and subtotal in 233. The complications were so nearly identical in the two groups that no significance was primarily attached to the type of operation performed. The death rate for total hysterectomy was 2.98 per cent and for subtotal 1.71 per cent. One half of the deaths occurred among the 25 with chronic chlorosis. Infection of the wound was five times as frequent when the hemoglobin was low and six times more frequent in the chronic chlorotic group. Ileus occurred three and one half times more often in the total anemic group and five and one half times more often in chronic chlorotic cases. Phlebitis was twenty five times more common in the chlorotic group, a low hemoglobin is considered to be the main contributory factor. Pulmonary complications showed a similar alarming incidence. The sum total of all complications showed an incidence of 17.5 per cent of postoperative lesions per hundred operations among those with a normal hemoglobin content 90.7 in the total anemic group and 13.6 in the patients with chronic chlorosis. When a definite diagnosis of chronic chlorotic anemia is established, the only satisfactory form of therapy is massive doses of iron.

Chronic Brucellosis—Davis believes that the chronic form of undulant fever is prevalent among the rural population, but as its recognition is more difficult it for the most part is overlooked. It is estimated that 10 per cent of the rural population is infected. The two common symptoms shown in all cases are weakness and pain. The patient gets up tired and feels as if the morning will never end. By noon he gains strength and by

evening he feels pretty good. The weakness is usually referred to the hips and knees. Spells of sleepiness may accompany the weakness as in epilepsy, which must be ruled out. Neurasthenia is the usual diagnosis given this phase of brucellosis. The pain, which is common to all cases, may affect any member of the body. It may be a headache or a backache. It may have the subjective symptoms of a herpes zoster without a cutaneous manifestation. In the extremities it may be very excruciating and appear to be a neuritis. At times the pain localizes about a joint and arthritis is thought of. Pain in the chest has had little mention in the literature, but in the author's experience it has been one of the most common and persistent symptoms. It is usually described as precordial, the history usually suggests angina pectoris. However, many differences are present: a low blood pressure, the youth of most of the patients, absence of arteriosclerosis and orthopnea. A paroxysmal tachycardia with a pulse rate as high as 160 per minute may develop at any time. The tachycardia is not always accompanied by an increase in chest pain. Large doses of sedatives are required to produce sleep. The symptoms do not respond to digitalis, aminophylline or the circulatory dilators. Two other conditions that accompany many cases are pelvic disorders and colitis, usually associated with constipation and mucus in the stools. Davis believes that the final diagnosis of chronic undulant fever should be made from clinical observation and confirmed by a therapeutic trial of vaccine rather than by laboratory tests. The vaccine must never be given subcutaneously, as cold abscesses often result. It should be given intramuscularly and, if induration appears at the site of injection, treatment should be suspended until absorption takes place.

Retinitis Pigmentosa J H McNamee Des Moines—p 421

Hypothyroidism and Heart Disease—In discussing the relationship of hypothyroidism to heart disease Smith points out that the myxedematous state speeds up the development of coronary and general arteriosclerosis. Thyroid should be used with caution in any case of myxedema as it may cause rapid relief or aggravate decompensation or heart pain. It has apparently precipitated death in at least 11 reported cases. The onset or aggravation of decompensation or angina should serve as a warning to reduce or discontinue thyroid medication. This dual potential effect of thyroid in myxedema should be borne in mind. It may accomplish much for the heart by clearing up the reversible harmful effects of myxedema or it may precipitate decompensation, pain or infarction by increasing the work required of a heart handicapped by coronary sclerosis. If heart failure in myxedema does not respond to the usual measures, it may be cautiously administered thyroid. Thyroid medication can retard arteriosclerotic degeneration in patients with myxedema. It may also delay arteriosclerosis in patients with less severe degrees of hypothyroidism.

Arc Welding Fumes and Gases—To determine whether the susceptibility of animals to tuberculosis is influenced by the fumes and gases of arc welding, Gardner and McCrum infected guinea pigs with the attenuated strain of tubercle bacillus, strain R₁, by inhalation and then exposed them to concentra-

tions of welding fumes and gases two to three times a day for one year. Generally, repeated exposures to ordinary concentrations did not increase the natural susceptibility and did not reactivate preexisting partially healed pulmonary tubercles to produce progressive tuberculosis. These data are valid for man as well as guinea pigs, as the effects of this irritant were identical with those observed with dusts of marble, soft coal, gypsum and iron ore. Prolonged exposure did not result in any unusual amount of tuberculosis. However, guinea pigs were more susceptible than white mice and white rats. Chemical pneumonia developed in 50 per cent of the exposed guinea pigs and proved fatal in about half of them. In spite of this severe irritation there was no significant effect on the associated primary infection with the attenuated tubercle bacilli. Tubercles developing during exposure were larger, more numerous and localized in different parts of the lung than in unexposed controls. However, they healed at the same rate as those in the controls and never manifested the slightest tendency to become progressive.

Celiac Disease—The data from a study of 40 patients with celiac disease treated by May and his associates during the last four years with a combination of crude extracts of liver and the B complex of vitamins show that benefit was irregular and usually only partial when any one of the substances was used alone. But definite improvement in the absorption of vitamin A and the clinical condition was invariably obtained in a relatively short time when both extracts were given intramuscularly in large amounts. The authors have no evidence as to the means by which absorption from the intestine in celiac disease is improved by the two extracts. One obvious hypothesis is that some defect in the phosphorylation process in the mucosa is the cause of the impaired absorption. On this premise some factor or factors in the crude extracts might be considered to play an indispensable role in phosphorylation. The treatment consists in 2 cc of liver extract injected intramuscularly into the buttocks one day and 4 cc of the B complex the next day in the alternate buttock. If induration occurs and persists, a day of rest is given. The injections should be continued for three weeks or until definite clinical improvement is observed. After this vitamin B complex should be given orally, at least 1 teaspoon four times a day until all the features of the celiac disease have disappeared. If improvement is not maintained by oral therapy, another series of parenteral injections is indicated. Most patients were given a normal diet from the very outset of treatment. The usual supplement of vitamins A, D and C should be given preferably in amounts twice the accepted daily requirements.

Sulfathiazole in Treatment of Measles—The value of sulfathiazole in the treatment of measles and the prevention of its complicating infections caused by streptococci, pneumococci and staphylococci was studied by Gibel and Litvak at the Kingston Avenue Hospital during the measles epidemic of December 1940 to June 1941. It was the most extensive epidemic of measles that greater New York has ever experienced, 79,637 cases were reported to the health department between January and June 1941. During this epidemic 1,213 cases were treated at the Kingston Avenue Hospital. All patients less than 6 admitted to the measles service were divided into two groups: one group was treated with sulfathiazole and the other group was treated symptomatically. The only exception to this was that all patients admitted with bronchopneumonia were treated with sulfathiazole. There were 201 cases in the control group and 200 in the sulfathiazole group. The course of the disease itself was not influenced. The common secondary complications (catarrh, bronchitis or purulent otitis media) did not respond to chemotherapy, while bronchopneumonia responded promptly, although bronchopneumonia developed in 6 previously uncomplicated cases during chemotherapy. The period of hospitalization was not reduced by using sulfathiazole. There was only one death among the 47 patients whose measles was complicated by bronchopneumonia.

Pitressin and Adrenal Cortex Extract in Diabetes Insipidus—Anderson and Murlin undertook studies to determine whether or not the already existing polyuria of diabetes insipidus of undetermined etiology in a boy of 9 would be aggravated by adrenal cortex extract. The study has confirmed the physiologic antagonistic action of adrenal cortex extract and pitressin on the excretion of sodium, chloride and water in the human subject with diabetes insipidus. Adrenal cortex extract did not increase the excretion of potassium unless pitressin was supplied. The suggestion is offered that facultative reabsorption of water as induced by pitressin must be in progress before the kidney tubule can selectively excrete sodium and potassium ions.

Prefrontal Lobotomy in Certain Abnormal Mental States—The results following prefrontal lobotomy in approximately 500 cases of certain mental disorders in this country and abroad indicate that the most suitable patient is one who is suffering from a persistent and intense degree of anxiety or apprehension. However, as anxiety may be present in almost any of the abnormal states, Drake and Hibbard find that the best response has followed in anxiety states, obsessive-compulsive reactions, agitated depressions and agitated schizophrenia. The results have not been so good in chronic encephalitis, chronic alcoholism and chronic schizophrenia. The more intelligent the patient, the better is the response. In considering the operation the degree of anxiety versus the possible postoperative defects and sequelae must be weighed. A most important feature is the fact that the intelligence is generally unaffected. There is often an apparent inability to foresee accurately the results of a series of planned acts as they relate to the individual himself. He becomes satisfied with something less than perfection. Memory for recent events shows transitory disturbance but for remote events it remains intact. Complete relief of symptoms in a case of anxiety neurosis following prefrontal lobotomy is reported by the authors. The operation should be performed only on those patients who have proved refractory to other forms of therapy and whose outlook is poor for ultimate recovery.

*Differential Diagnosis of Benign and Malignant Ulcerating Gastric
Lesions H M Pollard and W C Scott Ann Arbor —p 754

Ulcerating Gastric Lesions—According to Pollard and Scott, the differentiation of benign from malignant ulcers of the stomach requires the full cooperation of the patient, the clinician, the laboratory, the roentgenologist and the gastroscopist. Helpful inferences may be had from the history, but no absolute opinion is possible. A physical examination is not always helpful. A gastric analysis gives absolute aid in that an ulcerating lesion with persistent achlorhydria must be regarded as malignant. The original roentgen study, while of great importance, does not always establish the diagnosis accurately. Gastroscopy is frequently a valuable adjunct, but it is not infallible. A careful follow up examination, after a carefully supervised period of medical treatment, is of the greatest importance. Persistent occult blood in the stool should suggest a malignant status. Anything but complete relief from symptoms is of no value as a differential point, and this may occur in carcinoma. Complete healing as depicted in the roentgenogram is highly suggestive of a benign lesion but can also occur in a malignant one. The only safety lies in thorough investigation at every stage of the diagnostic procedure and in following the patient to complete sustained healing when the final diagnosis of benign gastric ulcer implies that there no longer is an ulcer.

Black Widow Spider Bite Syndrome—A heretofore undescribed sign of arachnidism, a burning and stinging sensation of the soles of the feet twenty-four hours after the bite was observed by Frank in 12 cases encountered during the fall maneuvers with the First Army in the Carolinas. Other than this new sign the syndrome was typical. He suggests using a mosquito bar or netting as an effective control measure. Spraying with crude oil or a mixture of crude oil and creosote will kill the spider. Powdered unslaked lime and kerosene will kill the adult spider in thirty seconds. All webs should be thoroughly sprayed. Such places as open latrines should be suspected and thoroughly coated. The spider is very dangerous after spraying, when it becomes agitated. Personal experience among the officer group in the author's regiment who used mosquito netting revealed the protection afforded it was not uncommon to see

one or even two black widow spiders crawling on the mosquito netting in the morning.

Fatal Coronary Occlusion in Apparently Normal Soldier—Sterling discusses the death from coronary thrombosis of an apparently physically normal soldier of 25 who suddenly died during a three day motor march unattended by great physical strain. At necropsy the arteriosclerotic changes were similar to those found in much older persons. The soldier was seen at the regimental dispensary in the bivouac area on the second evening of the march. He complained of general weakness and abdominal pain of several days' duration. Examination revealed nothing abnormal, and after a few hours of rest the patient returned for reexamination, at which time a definite bradycardia of 60 per minute, a soft presystolic apical murmur and a transient arrhythmia were present. Epigastric pain, which was not increased by mild exercise, was also present. The patient was given a sedative, was restless during the night, had nausea and desired to defecate. At 2:30 a.m. he was feeling better, at 3 a.m. he had struck his shelter tent with the other men and was rolling his pack, when he suffered an acute attack of dyspnea and pain and became convulsive and moribund. All available measures were ineffective, and he died at 4 a.m. At necropsy severe infarction of the left ventricle and interventricular septum with severe arteriosclerosis of the lower abdominal aorta and of the coronary arteries were present.

Erythema Nodosum—Poppel and Melamed say that during the years 1928-1941 88 patients were discharged from the Mount Sinai Hospital, New York City with a diagnosis of erythema nodosum. These cases were reviewed from two standpoints to analyze the clinical data from the point of view of associated diseases and to determine whether any specificity to the mediastinal or hilar adenopathy, or both, is shown roentgenologically. The survey indicates that the condition may be found during the course of various diseases, both infectious and noninfectious virus bacterial, chemical and toxic. It is evident that no common agent causes these diseases. In a small group of patients (approximately 15 per cent) no evident associated disease was present. Associated with the erythema nodosum were tuberculosis (4 cases), rheumatic heart disease (7 definite and 10 questionable cases), ulcerative colitis (6 cases), upper respiratory infections (49 cases), arthralgias (28 cases), drug

ingestion (8 cases), inactive syphilis (4 cases), gonorrhea (4 cases), herpes zoster (1 case), measles and otitis media (1 case), eye disease (1 case), prostatic abscess (1 case), postoperative infection of the abdominal wall (1 case), axillary abscess (1 case) and peritonsillar abscess (1 case). Fourteen of fifty-five available chest roentgenograms revealed positive intrathoracic findings. Twelve showed slight to moderate enlargement of the nodes, three with calcification. Pulmonary abnormalities were noted in 5 cases: resolving pneumonic process, pneumonic infiltration, exaggerated pulmonary markings, miliary tuberculosis and fibrocalcific tuberculosis. Tuberculin tests, which were performed on 12 of the 14 patients, were positive in 11. The patients whose roentgenograms showed intrathoracic adenopathy or pulmonary infiltration, or both, had associated disease of the respiratory tract that could account for the abnormalities and often obviously did. In the cases in which the development of erythema nodosum was associated with ulcerative colitis, prostatic abscess, peritonsillar abscess, rheumatic heart disease, gonorrhea, conjunctivitis, postoperative infection, axillary abscess, measles and otitis media and ingestion of drugs, the chest roentgenograms failed to demonstrate any pulmonary changes or intrathoracic lymphadenopathy.

Mebaral in Treatment of Epilepsy—According to Cohen and Myerson, the drug known in this country as mebaral was introduced in Europe under the name of prominal, the chemical formula being *n*-methyl-ethyl-phenyl barbituric acid. It has been used in Europe quite extensively. After reviewing the results obtained by some European and British observers, the authors say that this drug seems by far the best sedative in agitated depressed and anxiety states, since it produces more tranquility and less narcosis than any other drug, and without untoward symptoms unless given in doses above 0.4 to 0.6 Gm (6 to 9 grains) a day. The authors think that the drug is particularly useful for epileptic children who prefer tasteless medication for psychotic epileptics who must be treated by medication concealed in their food, for patients who cannot be given adequate phenobarbital because of toxic drowsiness and, finally, for trial on patients who do not show satisfactory response after trials of phenobarbital, phenytoin and bromides, separately or in combination. In certain cases relatively refractory to other medication, significant improvement was noted when mebaral was utilized. Mebaral was found to be less productive of toxic symptoms than phenobarbital or phenytoin, and a proportionately higher dosage was continued with safety and as great or greater clinical effectiveness. In the private practice of one of the authors mebaral has become the drug of first choice for the treatment and control of grand mal and petit mal. In cases in which it does not work well by itself, it combines well with phenytoin. In cases in which it is not effective, it is discarded, and phenobarbital and phenytoin in combination are used.

Segmental Enteritis—Robbins and Dreskin subjected 4 patients with regional enteritis to primary resection and transverse ileocolostomy. The first patient, a poor operative risk on admission, died on the thirty-sixth postoperative day of exhaustion, fecal fistula and subphrenic abscess. Two were discharged in two weeks in good condition with no complications except milk diarrhea in 1. The last 1, discharged after five weeks of convalescence, is free from symptoms at present. After review of the literature and of their experiences the authors believe that their first patient might have had a successful outcome with a simpler procedure of transverse ileocolostomy

with exclusion and abdominal chemotherapy. The fact that 2 of the patients had had an appendectomy is in agreement with Shapiro's review, which revealed that 112 of 413 patients had had an appendectomy. Therefore when patients with an appendectomy scar continue to have lower intestinal complaints segmental enteritis must be considered in the differential diagnosis.

Malaria in Infancy—Reisman and Schneek report the case of quartan malaria in an infant of 3 months which presented the problem of whether or not the malaria was a true congenital infection. At delivery there was no present known history of malaria in the mother. The infant's infection may have been congenital by way of the placenta or acquired when 20 cc of the mother's blood was given intramuscularly because of a difficult delivery. The mother had a history of infection and an apparent cure ten years previously with no apparent subsequent symptoms. The symptoms and signs of malaria in the infant subsided after quinine therapy was instituted.

**Concurrence of Death from Certain Diseases Among
Spouses**—According to Cicco, the records of 2,346 policy-
holders, referring specifically to the cause of death of 2,346
parental couples, reveal that the relative number of persons who
die from the same cause as the spouse is significantly higher
when the spouses died of tuberculosis, influenza, pneumonia or
cancer than when they died from other causes With tubercu-
losis the number is three to six times as high among spouses
of persons who died of tuberculosis as compared to spouses of
persons who died from other causes With respect to influenza,
pneumonia and cancer the number is one and four-tenths
to one and eight-tenths times as high among the spouses of
persons who died of these diseases as for the spouses of persons
who died from other causes The data do not corroborate the
marital association regarding mortality from heart disease

Bacterial Meningitis—Since Roberts has employed inten-
sive chemotherapy, 7 patients with bacterial meningitis have
come under his care and only 2 have died The ages of the
living children were 8, 5 and 3 years, 16 months and 10 months
The 2 children who died were 12 and 9 months old, respectively
This experience and that of others indicates that chemotherapy
is the treatment of choice Favorable reports have been pub-
lished with the use of sulfamilamide, sulfapyridine, sulfathiazole
and sulfadiazine Because of the tendency of the infection to
relapse, medication should be continued for ten to fourteen days
after the spinal fluid is normal High concentrations of the
drug, 40 mg and more per hundred cubic centimeters of blood,
are tolerated by the host and may be the important factor in
sterilizing the spinal fluid The author's failure to sterilize the
spinal fluid of 1 of the infants with influenzal meningitis who
died with concentrations as high as 92 and 78 mg per hundred
cubic centimeters in the blood and spinal fluid, respectively,
seems to indicate drug resistance

Familial Hemolytic Jaundice—During the last five years
McLaughlin encountered 30 cases of familial hemolytic jaundice
and advised splenectomy in 16 because of clinical and laboratory
evidence that the disease process was not latent The 13
persons who accepted this advice and have successfully under-
gone splenectomy came from nine unrelated families The aver-
age age of the 13 was 25 years, the oldest being 40 and the
youngest 5 Females predominated in the ratio of 2:1 The
main presenting symptoms were weakness, fatigue and jaundice
in all but 2 patients This is evidence of the constant destruc-
tion of blood and associated icterus Fever, chills nausea and
vomiting were attendant symptoms of those admitted during the
active phase of the disease The spleen was readily palpable in
each of the 13 The principal complications of familial hemo-
lytic jaundice were acute hemolytic crises or "crises of deglob-
ulization" There is a tendency for several affected members
in a family to experience these episodes within a few days of
one another with a possible reduction of the erythrocytes below
levels of one million The sudden and striking increase in the
cellular elements of the blood during splenectomy is one of the
most interesting features of this condition There was a uniform
rise in hemoglobin during operation and in the hour following,
which averaged 232 per cent The erythrocyte counts cor-
respondingly rose during this period The average increase
was 1,100,000 cells Both the hemoglobin and erythrocyte read-
ings then gradually fell during the next two days and then
gradually increased to normal in almost every case at the end
of the first postoperative month The leukocyte counts also
became elevated during splenectomy but this leukocytosis gradu-
ally decreased during the postoperative period These changes
in the blood picture are characteristic of familial hemolytic
jaundice during and following splenectomy The probable
explanation is a sudden outpouring of cells into the peripheral
circulation from an enlarged splenic reservoir which is com-
pressed and manipulated during the surgical procedure This
initial autotransfusion is the factor which permits successful
splenectomy in the presence of profound anemia or a crisis with-
out resorting to transfusions Following splenectomy trans-
fusion is safe but is rarely necessary There has been no
recurrence of the hemolytic factor in any of the 13 patients fol-
lowing splenectomy If hemolysis reappears after splenectomy it
may be assumed that the original diagnosis was incorrect, that
overlooked splenic tissue has become active or that hemolymph
nodes have hypertrophied and assumed a hemolytic character

Chronic Biliary Typhoid Carriers—Coller and Crabtree state that until the chronic typhoid carrier is recognized and completely managed or cured epidemic typhoid will continue to exist. The four places in the human body in which typhoid bacilli may remain and give rise to the carrier state are the urinary bladder, the intestinal mucosa, the biliary radicles of the liver and the gallbladder. Chronic carriers are those who harbor microbes for a year after infection. At present in Michigan there are 275 carriers on the typhoid registry, but on the basis of some statistics there should be around 3,600 designated carriers. This may be high, but when one considers that 2 to 4 per cent of all typhoid patients become permanent carriers it is a most probable figure. There are four methods to eliminate and control these unfortunates: negative stool and bile specimens, routine examination of urine and stool specimens from all food handlers, epidemiologic investigation of all sporadic cases of typhoid and routine examination of fecal or urine specimens from patients suffering from other illnesses and the culturing of bile from all gallbladders removed at operation. As regards their treatment at present in Michigan the eligibility criteria for operation and release of chronic biliary typhoid carriers are as follows: For a carrier to be operated on primarily for the cure of the carrier state he must be a chronic bile carrier and a good surgical risk. The eligibility criteria for release after cholecystectomy are twelve consecutive negative feces specimens obtained at monthly intervals and one negative bile specimen obtained during the postoperative year. Since 1937 the authors have studied 21 chronic biliary typhoid carriers before and after operation. The gallbladder of each was examined pathologically after its removal, and evidence of some chronic inflammation was found in all. The authors feel that 16 of the patients are definitely cured, though release bile specimens are not at hand for all of them. In 3 additional patients who have had their operations recently the first several stool specimens have been negative and no doubt in time they will be classed as cured. The 2 patients who are not cured probably belong to that small group of carriers in whom the biliary radicles of the liver are infected. The postoperative bile specimens have been positive in both. From an analysis of stool cultures obtained after operation in the cured group two types of chronic biliary typhoid carriers were revealed: one in which the gallbladder alone was the focus of infection and one in which there were apparently smaller additional foci in the intestinal or the biliary tract. In the former the stool cultures become free of typhoid bacilli soon after operation. In the latter there is a definite delay (up to two hundred and sixty-seven days). Apparently, the additional foci were freed of typhoid bacilli by the powers of the body alone after the major source of the infection, the gallbladder, had been removed. In such patients a trial of one of the sulfonamides is suggested in the hope that it may hasten the destruction of any remaining typhoid foci within the intestinal tract.

First Aid Prophylactic Treatment of Compression Syndrome—Patey and Robertson believe that the crush syndrome may be due to loss of blood constituents from the circulation into the tissue of the injured limb rather than to a release of a toxin from a crushed limb. They therefore aimed at restoring extravasated fluid back from the edematous limb into the circulation by intermittent positive pressure up to 60 mm. of mercury. They treated 2 cases successfully. There is experimental support for the new conception and routine treatment appears justified. For the application of the principle in first aid treatment an elastic web bandage of 3 inches is ideal. If this bandage is applied from below upward, stretched to double its unstretched length and each turn partially covers the previous turn so that only $\frac{3}{4}$ inch of the lower edge of the latter projects below the fresh turn an approximate pressure of 40 to 60 mm. of mercury is obtained. The bandage should be applied direct to the limb without the intervention of clothing. The stretch can be assessed by marking the lower edge of the bandage at half inch intervals and then doubling the markings on application. The foot or the hand of the injured limb should be included in the bandage to avoid edema in any part of the limb. After admission to the hospital, if the bandage has been immediately and correctly applied no further local treatment is required. The bandage should probably stay on for some days and possibly then be reapplied at slightly less pressure. First aid parties should be taught to apply the bandage properly, and immediately the limb is released from compression.

Relapsing Fever in Addis Ababa—Robinson states that 340 cases of relapsing fever were observed in Addis Ababa during the second half of 1941. That *Spirocheta obumbrata* was transmitted by the body louse was substantiated by the facts that mixed infections of relapsing fever and louse borne typhus were common; spirochetes were often found in crushed lice collected from patients with relapsing fever and ticks were not found, nor was there a single case in which the "tache noir" (the primary tick bite sore) was observed. All the patients were treated immediately and responded admirably to neocarphenamine. In about 6 per cent malaria was concomitant and the quinine treatment did not interfere with the neocarphenamine. Jaundice, hemorrhage from the mucous membranes, occasional bleeding in the central nervous system, edema, acute thyroiditis, parotitis, perisplenitis and pachymeningitis were the

complications encountered. Relapses occurred in spite of treatment in 16 per cent one relapse and in 4 per cent two relapses. The longest interval was twenty seven days. One, two or three injections of neurosphenamine were necessary. Hemorrhages, if severe must be treated. The prothrombin time was prolonged in every instance even if not complicated by hemorrhage. Vitamin K proved to be the ideal treatment. The author thinks that 5 to 10 mg of menadione in oily solution intramuscularly should be given to all patients with relapsing fever to prevent hemorrhage. The case mortality was 35 per cent, and at necropsy peritonitis was present in almost every instance and sometimes splenic infarcts. Endocarditis was common.

Alcohol Diuresis in Man—Eggleston determined the diuretic action of alcohol and its mode of action by simultaneous analysis of the concentration of alcohol in the blood and urine of 5 subjects. The diuresis following an alcoholic drink was roughly proportional to the amount of alcohol present when volume and other constituents were maintained at a constant level. Variations in external temperature seriously affected this relationship that is cold caused a greater diuresis. Its onset was delayed for twenty to thirty minutes after the drink was taken, and its height was unrelated in time to the peak of blood alcohol concentration. The diuresis could be completely inhibited by ablation of posterior pituitary. It was inhibited by the increase in blood alcohol concentration and failed to be maintained if this concentration was kept steady, even at a high level. The degree of diuresis from a given dose of alcohol varied widely in different subjects and was dependent on the natural rate of absorption of alcohol and water and possibly on a variation in the sensitivity of the pituitary mechanism. The diuretic response to alcohol and that of the cerebral cortex differed in one respect, the latter was most affected by the rate the concentration of alcohol in the blood was increased. The greater this increase was, the greater was the disturbance of function at any absolute concentration, but with the diuretic response the duration of the increase and not the rate of increase was important. When an equilibrium has been established in the body the concentration of alcohol in the urine remains 30 to 35 per cent higher than that in the blood. Comparison of these values with the arterial and venous blood and plasma indicated that the alcohol in the urine was in equilibrium with that in the water of plasma.

Air Entry Through Transfusion Sets—Recently several deaths from air embolism following transfusion were encountered by Devas. Under certain conditions large quantities of air can be pumped into a vein through a transfusion apparatus working solely by gravity. For preventing such an eventuality he suggests that the screw clamp, instead of being on the rubber

tubing between the blood bottle and the drip chamber, should be clamped on the tubing only 2 or 3 cm above the needle in the vein. In this position the rate of flow is just as easily controlled but in addition there will be a positive pressure in the apparatus above the clamp and any leak occurring will cause fluid to flow out and not air to flow in.

Neurosis in England Under War Conditions—According to Lewis it is not easy to decide whether a mental disturbance is directly attributable to war conditions and particularly to air raids. It is therefore more informative to find out whether there is more or less neurosis altogether since the war or since the intensive air raids than to count up the cases that seem to have been caused by the war. Data have been collected in different British cities by doctors, hospitals and outpatient clinics. In the summary it is stated that air raids have not been responsible for any striking increase in neurotic illness. Crude figures from hospitals and outpatient clinics even suggest a considerable drop, the figures of the Ministry of Pensions however give a better indication of the problem. Reliable data from London and Bristol and the impressions of medical observers indicate that after intensive raids there is a slight rise in the total amount of neurotic illness in the affected area occurring chiefly in those who have been neurotically ill before. Neurotic reactions may not show themselves for a week or ten days after the bombing, they usually clear up readily with rest and mild sedatives. Hysteria is uncommon, anxiety and depression are the commonest forms of upset. The incidence of neurotic illness has been low in firefighters and other workers in civil defense. Insanity has not increased as far as figures are to hand, though more persons with senile deterioration have been admitted to mental institutions than before because their relatives could not any longer look after them or because the raids had in other ways disturbed their routine and their precarious adaptation. The same was true of some defectives. Suicide has diminished in Scotland, especially among the middle aged and elderly. Figures for England and Wales are not available. It is impossible to distinguish between neurotic illness due directly to air raids and that which may follow such secondary troubles as disruption and loss of one's home, evacuation, difficulties in transport to and from work or temporary loss of employment. It is to the war as a whole with its accumulated stresses, that people have had to adjust themselves and signs of failure to do this can be taken as warning signals of neurosis. An increase in alcoholism would be such a sign, there is no evidence that there has been any increase of this sort. The rise in road and industrial accidents has been considerable, many causes are at work, the psychologic ones among which have not been analyzed. There has similarly been a rise in juvenile delinquency, this cannot be regarded as tantamount to a rise in juvenile neurosis, but it suggests that the same environmental factors are at work as conduce to neurosis.

Hypochromic Anemia During Pregnancy—Hamilton and Wright believe that physiologic changes in blood volume and the demands of the fetus on maternal iron reserves render hypochromic anemia especially frequent during pregnancy. The characteristic decrease in hemoglobin percentage accompanied by a fall of the same degree in the red cells makes the estimation of hemoglobin the best guide to the adequacy of the woman's iron reserves. The object of the present investigation has been to determine whether the current wartime dietary restrictions have had any detrimental effect on the hemoglobin concentration of the blood of women during pregnancy. Repeated hemoglobin estimations by the Haldane method have been carried out on 392 pregnant women from about the third month of gestation until term. Half of the women examined were treated with medicinal iron throughout the period of observation while the rest had no such medication. The average

initial hemoglobin percentages were 79 in the untreated and 75 in the treated group. The corresponding average terminal percentages were 70 and 77, so that iron administration converted a deterioration during pregnancy into an improvement. From comparison with other published figures it is concluded that women of the artisan class are more anemic than before the war. Iron preparations should be given as a routine during pregnancy, and antepartum clinics should help expectant mothers to select and prepare iron rich diets.

Roentgen Therapy in Experimental Gas Gangrene Infection—Experiments on mice infected intramuscularly in the thigh with *Clostridium welchii* and *Clostridium septicum* and then only irradiated or irradiated and also given a local application of sulfanilamide powder revealed to Singer that irradiation did not prolong their survival. The infecting dose and the amount of sulfanilamide were so adjusted that the infecting dose alone would kill all mice within twenty-four hours, while when it was injected with sulfanilamide only some of the animals died. Mice infected with culture alone or the ones injected with the culture and also given sulfanilamide were not benefited by roentgen therapy. In view of these results it is difficult to understand why certain clinicians report enthusiastically on roentgen therapy in the prevention and treatment of gas gangrene in human beings. The fact that *Cl. welchii* occurs as a normal saprophyte in the intestine, on the mucous membranes and on the skin of many normal people and that gas gangrene is rarely a primary infection of a wound makes it clear that misconceptions of the action of a therapeutic procedure can arise in various ways. Suppurating or clean wounds in which *Cl. welchii* or some other anaerobic bacillus can be demonstrated apparently respond satisfactorily to such treatment. Actually the gas gangrene organisms were present only as saprophytes and the wound would have healed without treatment. Irradiation favorably influences only low grade localized infections. However, sulfanilamide and antitoxic serum act favorably on the virulent type of gas gangrene infection. Serum acts only on the toxemia, while sulfanilamide kills or prevents the multiplication of bacilli. As the diffusion of the sulfonamides is slow and blood clots and dead tissue are not readily penetrated locally they would have more a prophylactic than a true therapeutic action. Furthermore, as their penetrative power varies considerably, local treatment of fully developed gas gangrene in which the bacilli are widely dispersed would be ineffectual. When used locally only the pure crystalline substances or some form especially suited for local application should be employed. Crushed tablets contradict all surgical principles placing them in a wound after surgical debridement is nothing more than the introduction of foreign bodies into an area from which they were just removed.

Gastric Diseases in Military Service—According to Haemmerli, gastric disorders present a difficult problem in military medicine because of their chronicity and tendency to relapse or to develop on the basis of a hereditary predisposition. The stomach is greatly exposed to the damaging influences of daily life, infectious diseases and chronic focal infections. The stomach is influenced more than any organ by the psyche and the sympathetic nervous system. Dyspepsia is the most frequent symptom of patients with gastric disorders. A review of the records of 500 patients with this symptom disclosed that 66 per cent had gastric disturbances, while in the other 34 per cent the primary disorder involved the liver, gallbladder, circulatory organs, kidney and other organs. The author reviews the results of the roentgenologic examination of the stomach in 1608 military patients. Roentgenoscopy is indispensable in the diagnosis of ulcers. The form of the stomach, its tonus and peristalsis often give information about the sympathetic innervation of the organ. Roentgenoscopy is not reliable in the diagnosis of gastritis. Hyperacidity or hypoacidity should not be designated as a disease. A single fractionated gastric aspiration gives little information, only comparative tests over weeks or months are of value. Frequently the entire symptomatology consists of functional disturbances, a manifestation of an impaired innervation and often a part of a general dysfunction of the sympathetic nervous system. This dysfunction may be hereditary or acquired. The anatomic lesion, the ulcer, is only one aspect of the diathesis. Under military conditions, treatment must be limited to this anatomic lesion. In some ulcer patients the diathesis develops on the basis of a hereditary predisposition. There is a type of ulcer that is a sequel to vascular disease such as arteriosclerosis or syphilis. Inadequate chewing was the causal factor in about 14 per cent of cases of gastritis. Correction of dental defects and improvement of hygiene of eating will counteract these disorders. Heavy meals immediately after great exertion may lead to gastritis. The military physician must see to it that when men are exhausted they receive easily digestible food. A heavy meal should be served only after they have recuperated to a certain extent. Abuse of nicotine is another frequent cause of gastritis. Whereas alcoholic gastritis has practically disappeared among soldiers, nicotine gastritis has greatly increased. The therapy of gastritis is difficult when a focal infection exists or after infectious diseases. Gastritis with anacidity represents an important group, the function of the mucosa must be investigated by a test meal. Gastric lavage in the morning has proved effective. There are soldiers with hypersensitivity to certain foods or with other allergic condition for whom effective treatment is hardly possible during active service. Approximately 15 per cent of patients with gastric disorders suffer from "nervous dyspepsia" and its sequels, which is a digestive disturbance produced by dysfunction in the vegetative nervous system, which in turn is brought on by a disturbance in the mental equilibrium or by disharmony in the organism due to faulty mode of living. Conditions connected with the person's occupation are often the provoking causes. Many cases of nervous dyspepsia can be readjusted by adoption of a more suitable mode of life. In some instances military service produces a desirable change and restores balance, in others it intensifies the existing disorder.

Evaluation of Fitness of Gastric Patients for Military Service—Demole reports that in November 1940, at a session of the gastroenterologists of Switzerland, a committee presented to the health service of the army rules to guide military physicians in estimating the service capacity of patients with gastric disorders. Patients with gastric tumor are to be definitely excluded from the army, also those who have undergone a gastric operation and who continue to have complaints. Some who have undergone gastrectomy or gastroenterostomy can be utilized in the army provided the necessary precautions are taken for their alimentation. The patient with a verified gastroduodenal ulcer is for a long time unsuited for military service. Acute duodenal ulcer may heal completely under attentive treatment. At the end of six months the patient can be examined again for a new decision. A radiologic niche on the small curvature of the stomach is more refractory, and a man with such a lesion cannot return to the service for about two years. Patients with chronic ulcer and periodic recurrences must be excluded from the army in order to avoid the risk of serious complications. Nothing is more difficult than to declare an ulcer cured, the condition is likely to recur without apparent cause. Even the disappearance of the radiologic sign does not prove complete healing. Outside of the ulcer periods with regular postprandial cramps, the ulcer patient does not have an intact stomach. Gastritis is the rule in duodenal ulcer, the modifications of gastric acidity persist, the patient may have malaise, which cannot be ascribed to the ulcer as such. From 40 to 50 per cent of patients with dyspepsia have gastritis. They present a great variety of symptoms, and the roentgenologic aspect and chemism rarely provide conclusive evidence. Only gastroscopy gives information regarding the condition of the mucosa. In acute gastritis appropriate dietetic treatment may result in a cure. In chronic gastritis numerous etiologic factors may be encountered: irritation by tobacco or alcohol, tachyphagia and insufficient mastication, abdominal disorders such as appendicitis, cholecystitis and adenitis, and focal infections such as parodontosis and tonsillitis. In these cases military life may transform an old but latent dyspepsia into a more acute type. Severe forms of anacid atrophic gastritis resistant to treatment render a subject unsuitable for service. In patients with functional disturbances a thorough examination is essential in order to rule out an organic lesion and determine the nature of the disorder. In the presence of a nervous dyspepsia with absence of organic lesions and a tendency to neuropathia a psychiatric analysis might be advisable.

Gastric Patients in Military Service—According to Kapp, roentgenoscopy is the most important method in the diagnosis of gastric disorders. Negative roentgenoscopy does not necessarily indicate that there is no gastric disorder. The most frequent stomach lesion, gastritis, is only rarely detected by roentgenoscopy. Fractional aspiration of the gastric contents is helpful in the diagnosis of gastritis, particularly if proper attention is given to the presence of cellular elements in the gastric juice. Estimation of fitness for military service is difficult in men with gastric disorders. The mental attitude of the patient is an important factor. It has been found that in the front line and during offensive warfare hemorrhages and perforations from ulcers are not more numerous than under more normal conditions. The close connections between the nervous system and gastric disorders are realized more and more. Many of the so-called gastric neurotic, however, have a gastritis or an ulcer. It is impossible to render a final decision regarding the fitness for service until the gastric disorder has been definitely identified. Attention must be given to the correct distribution of meals. German military physicians call attention to the fact that the morning and evening meals are often too small in comparison with the large noon meal. They recommend that the noon meal furnish about 40 per cent of the daily intake and the morning and evening meals 30 per cent each.

Functional Examination of Heart—Holzmann demonstrates that the cardiac function is only the activity of one link in the chain of the circulatory organs and that circulation serves all life processes. The cardiac function becomes manifest

in the minute volume and in the pressure. Both of these factors are to a great extent dependent on the other links in the chain of the circulatory system. On the other hand a functional disturbance of the heart due to a myocardial impairment or to a defective mechanism may cause disturbances in the entire system. The numerous and close interrelations explain why the wish of the practitioner for a simple and universal functional test of the heart cannot be satisfied. From the clinical point of view a detailed history and a thorough examination are still the most essential factors in the estimation of the cardiac function. They can be supplemented by tolerance tests. Control of the pulse, the blood pressure, the respiration, the vital capacity and the electrocardiogram are important. They yield information that gives a better understanding of the functional capacity. The results of each individual test, however, are often equivocal and therefore easily misleading. If estimated together with other observations, they can be of value.

Circulation and Vegetative Nervous System in High Altitude Flying—Meier-Müller directs attention to the importance of the cardiovascular system in determining fitness for military aviation. The heart and circulatory organs must be examined with all available methods. Orthodiagram, electrocardiogram, radioscopy and tests in the low pressure chamber are absolute necessities in estimating the flying capacity. The behavior of the cardiovascular system under the abnormal physiologic and psychologic conditions of a flight at high altitude must be determined in the presence of oxygen deficiency, of low temperatures (up to minus 60 C), during great and rapid altitude changes, during accelerations up to 10 g (g = acceleration of gravity) and during the action of centrifugal and centripetal forces. The high altitude resistance test by means of the low pressure chamber may disclose the adequacy of the organic functions, but it would be a mistake to base estimation of fitness exclusively on clinical factors. Persons with healthy cardiovascular systems may fail under the exertions of wartime aviation, because "the nerves failed" because the man did not have the adequate psychic resistance because during moments of greatest concentration and demands on the sense organs, during mental stress and reduced circulatory and respiratory function, he failed physically and mentally. A normal heart, normal circulation and normal respiration are of little value in military aviation if the person does not also have adequate intelligence, a normal brain, a solid nervous system and a maximal psychic resistance. The author directs particular attention to the correlations between sympathetic nervous system and psyche. It has been demonstrated that the vegetative regulation of blood distribution under the influence of high altitude and of great accelerations is to a great extent dependent on the mental clarity and the integrity of the aviator. It was believed that great vasolability rendered a person unfit for the flying service. That was erroneous. Today, vegetative stigmatism for instance in the form of increased emotional irritability is no absolute reason for exclusion from the flying service. On the contrary some exploits in aviation, particularly in aerial combat, are accomplished by such emotionally hyperexcitable, vasolabile persons. A number of successful combat fliers exhibit a higher than average sensitivity of the vasomotor system. If vasomotor sensitivity is found in daring, keen and energetic personalities it constitutes no hindrance to flying service. However, if it is associated with unsteadiness, superficiality and lack of responsibility it is a cause for rejection.

Bol Inst de Med Exper p Cancer, Buenos Aires

18 929-1320 (Dec) 1941 Partial Index

*Electrosurgical Therapy of Cancer of Rectum A. H. Roffo and I. Carranza—p 1027

Electrosurgical Therapy of Cancer of Rectum—Roffo and Carranza treated 926 patients with cancer of the rectum. They advocate surgical therapy whenever the local lesion can be removed, regardless of metastases in remote organs, provided the general condition of the patient is satisfactory and there are

no contraindications. Operability and the type of operation are decided by a surgical exploration in the course of which inflammatory adhesions of the tumor are severed and the tumor can be seen and sometimes palpated. The prognosis is good when the tumor cannot be palpated or when it is palpated with difficulty. Local metastases perforation of carcinoma into the peritoneum and involvement of the prostate, the uterus and the vagina do not constitute contraindications to a radical operation. Perforation of the tumor into the bladder, metastases in the peritoneum and diffuse metastases in the bones contraindicate either a radical or a palliative intervention. A radical sacral operation is the operation of choice in low ampullar and anorectal forms. When the tumor is situated above the peritoneal fold and there is a reasonable segment of normal tissue in the lower part Hartmann's operation, by which the anorectal segment is not removed is to be preferred. The authors employ the two stage operation. The first stage includes colostomy examination of the rectum lavage and high voltage roentgen therapy. In the second stage the rectum is exposed by the sacrococcygeal approach and the bowel is divided by electrocoagulation technic of Goetze and the tumor is electrocoagulated. The peritoneum is not opened. Inoperable cases thus treated may become operable. When this is not the case the rectum is sectioned above the tumor which is then coagulated and removed with the involved lower segments of the rectum including the anus sphincter and fat of the perirectal space. The authors employed electrosurgical therapy in 261 cases with 50 per cent five year cures. There was an operative mortality of 2 per cent.

Tuberculous Mesenteric Lymph Nodes in Adults—Abdominal lymph nodes may become tuberculous early in life just as mediastinal lymph nodes do. Tuberculosis of the mesenteric lymph nodes is a reaction to a visceral lesion at the point of entry of the tubercle bacillus. It does not necessarily appear during childhood. To make the diagnosis of primary infection possible other organs must be carefully examined, because enlargement of lymph nodes may be present in other than the primary infection. In military tuberculosis, for instance, the tuberculous process may involve various groups of lymph nodes. Calvo Melendro differentiates several types of mesenteric lymph node tuberculosis. Clinical diagnosis of the primary lesion of the intestine is much more difficult than the diagnosis of the primary focus in the lung. Intestinal symptoms may be absent, palpation almost never succeeds, and roentgenoscopy is of no value in the beginning. Only after the lymph nodes have become calcified do they become visible in their typical location, which is the ileocecal angle. More or less localized abdominal pain may raise a suspicion. General symptoms such as fatigue, fever, general debility or loss of weight may direct attention to tuberculosis, localization may become possible in the presence of pain. The tuberculin reaction is important. The author observed the condition in 3 young soldiers. The men lived in rural regions until their entry into military service. They acquired the disease a short time after coming to a large city. The tuberculin reaction proved valuable in the diagnosis. In 2 of the patients the disease caused cachexia and terminated in death without dissemination of the tuberculous process. No information could be obtained regarding the outcome in the third case. The clinical features resemble the condition which the earlier authors designated as *tabes mesenterica*.

Lesions of Rectum and Bladder Caused by Radium Therapy of Cancer of Cervix—Chydenius reports observations on ray lesions of the urinary bladder, rectum and adjoining tissues following radium therapy of carcinoma of the uterine cervix in the course of treatment at the Central Institute for Irradiation in Finland during the years 1937 to 1940. There were 321 patients with carcinoma of the cervix uteri treated with radium or roentgen rays. Of these 33 exhibited late reactions on the rectum. The majority had mild changes in the rectal mucosa, but in 15 the lesions were severe. There were 4 cases with severe complications of the bladder. The distance between the tumor and the rectum varies greatly and, as a result, the doses of rays that reach the rectum are subject to great variation. Measurement of the dosage in milligram element hours is far from satisfactory in eliminating damage to adjacent structures. Variations in position of the rectum are demonstrable in roentgenograms. There is much room for improvement in the calculation of focus doses in radium as well as roentgen therapy. The author calls attention to his previous suggestions on isodoses computed in roentgens.

Mammography of Breasts with Pathologic Secretion—According to Frostberg, secretion from the nipple of a non lactating breast is sometimes the first sign of a pathologic process. There has been much discussion regarding the significance of such secretions. The suggestion that they indicate cancer has caused many unnecessary mastectomies. At the author's hospital at Norrköping, mammography has been employed since February 1939 for all breasts with pathologic discharge from the nipple. Fourteen mammographies have been done, and in all valuable information has been obtained as to the nature of the mammary process. The pictures were a valuable aid to the surgeon in cases in which resection was subsequently performed. The technic used was that described by Hicken in 1937. The contrast material required never exceeded 2 cc. Mammography should not be employed in inverted nipples because it usually fails. The author's attempts at mammography were unsuccessful in 4 cases. Mural papillomas and cysts were demonstrated. In 2 cases the roentgenogram suggested cancer. The value of mammography cannot be questioned.

Rotation Therapy—Nielsen and Hoeffler Jensen describe their experience with rotation irradiation. Experimental measurements were made with small condenser chambers on a thorax phantom and on an anatomic specimen. The depth dose for small stationary fields of less than 50 sq. cm. was measured for various ray qualities. A number of intensity distribution curves were reproduced, they showed that a central zone forming a cylindrical core about the axis of rotation receives a homogeneous dose considerably larger than that received by the surrounding peripheral zone. The fall in intensity from one zone to another is abrupt. The ratio of the maximum dose to the peripheral dose depends on the size of the field (the opening in the diaphragm) but is only to a limited extent dependent on the quality of the rays and the focus axis distance. The authors relate their clinical experience with rotation treatment in 8 cases of cancer of the esophagus. As a result of the small size of the fields made possible by the constant screening control the general condition of the patients was little affected. Daily doses of 1,000 roentgens given twice were tolerated without difficulty. Even with a total dose of 22,000 roentgens in the course of four weeks only a moderate erythema was observed. The primary effect on the tumor was good and the stenosis was overcome. The possibility of applying the rotation therapy to other tumors (cancers of the uterus, the rectum and the hypophysis) is discussed and the value of the screening control emphasized.

Book Notices

The Management of Fractures Dislocations and Sprains By John Albert Key M.D. Clinical Professor of Orthopaedic Surgery, Washington University School of Medicine St. Louis and H. Eric Conwell M.D. F.A.C.S. Orthopaedic Surgeon to the Tennessee Coal Iron and Railroad Company Birmingham Ala. Third edition. Cloth. Price \$12.50. Pp. 1103 with 1259 Illustrations. St. Louis: The C. V. Mosby Company 1912.

This book, written by two leaders in the field concerned is especially valuable during the war. In the present edition extensive changes have been made in sections devoted to fractures of the spine, humerus hip and foot. The chapter on compound fractures has been rewritten to include the great strides in chemotherapy. A section on war injuries has been added. There is an important chapter on the workmen's compensation law affecting fracture cases and another on the medicolegal aspects of fracture cases. The authors outline a list of the splints to be kept in a doctor's automobile and another list of splints to be kept in a doctor's office. These two lists are valuable especially in relation to civilian defense. The chapter on the principles of treatment of fractures is well done. Some of the best work of Colonel Hark of the Medical Corps of the U. S. Army has been reproduced with many of his illustrations. Cornwell's ladder splint is an effective device for emergency immobilization of fractures of the spine or pelvis and for visceral injuries. For compound fractures it is advised that the wound be exposed and a clean dressing applied at the earliest moment. This dressing not only lessens the bleeding but protects the wound from further contamination. It possible this dressing should include sulfanilamide or sulfathiazole or preferably a mixture of the two. The powder should be sprinkled liberally into the wound. For this reason these drugs should be made available in emergency dressing stations and in industrial plants and should be carried in doctors' automobiles and ambulances which are sent out for the specific service of picking up injured persons.

In the section on debridement the authors outline ten important points: excision of the skin margin enlargement of the wound, debridement of the wound proper treatment of the bone irrigation of the wound repair of the deeper structures reduction and internal and pin fixation of the fracture final inspection of the wound and control of hemorrhage chemotherapy of the wound and closure of the wound. The authors quote an interesting section on the avoidance of malpractice suits from a book entitled *Court and Doctors* by Stryker, who said that "the best way to avoid a lawsuit is not to deserve one." In the section on vertebral disk lesions the authors call attention to the wave of enthusiasm for the removal of a disk from all patients with low back pain and sciatica. These patients should not be subjected to spinograms and intraspinal operations until conservative treatment has failed to relieve their symptoms. Figure 973 is an excellent illustration of the apparatus for the application of Russell traction in the treatment of fractures of the shaft of the femur. In the treatment of dislocations of the knee the authors do not advise open operations because the ligamentous damage is so extensive that there is little chance of operative repair and the chance is not worth the risk incident to the operation.

In spite of the fact that the book is so valuable, it deserves some constructive criticism. Some of the illustrations, especially photographs and several of the roentgenograms, could be improved. Some portions of the book, such as the section on the foot, are not up to par. March fracture is given slight mention, and the section on Freiberg's infraction of the metatarsal head is inadequate. All in all, this is an excellent book and one of the finest on the subject. It should be in the library of every physician and surgeon, especially during wartime, when the military aspects are so urgent and civilian defense so important.

The Answer Is Your Nerves By Arnold S. Jackson M.D. F.A.C.S. With a Chapter by the Rev. Edwin O. Kennedy. Cloth. Price \$9. Pp. 197 with Illustrations by Evelyn Lipman. Madison Wisconsin: Kluge Printing Company 1942.

This book, written for patients, comes from an author of wide experience associated for many years with one of our largest clinics. He describes with accurate detail the hundreds of nervous patients both male and female who fill the clinic

waiting rooms almost to the exclusion of people with more structural evidence of disease. Case histories are cited, but many cover only a few days or weeks of the patients' illness, too short a time to evaluate the effects of therapy. Treatment is largely relaxation, particularly the muscular exercises of Jacobson—the back to the country type of change of environment, and common sense psychotherapy. There is some loose thinking such as "Some men shout and work themselves up to high tension when talking over the telephone long distance. Such tension merely raises the blood pressure and hardens the arteries" (p. 11). One of the best remarks comes from Carl Hubbell, star pitcher for the New York Giants: "Baseball is a fast game, but you've got to slow down to play it. And life is that way too I think" (p. 13). The illustrations by Evelyn Lipman are clear and delightful although grossly exaggerated to make the points.

The book is a light but frontal attack on a major medical problem and should help those who read it seriously. Some will object to the emphasis on muscular relaxation, but this is often the best prelude to psychotherapy and, if used in this way, it becomes a kind of voluntary 'mental alienation,' to use Sister Kenny's phrase, between our brain and our muscles. We may be putting the muscles in 'neutral' leave the brain more receptive to therapeutic ideas.

Microbiology and Man By Jorgen Birkeland Ph.D. Assistant Professor of Bacteriology, Ohio State University, Columbus. Being an Account of the Diverse Properties and Characteristics of Microorganisms as a Description of the Various Tools and Techniques for their Handling and an Inquiry into their Subtle Relationships to Everyday Life. Cloth. Price \$1. Pp. 478 with 44 Illustrations. Baltimore: Williams & Wilkins Company 1942.

The author's preface states that this is 'designed as an elementary textbook for the student who plans to take but one or two courses in microbiology. It is intended to serve as a basis for an understanding of the part played by microorganisms in everyday life. It is a guide for learning as well as a source book of facts.' The book is divided into four sections on fundamentals of microbiology, infection and resistance, common infectious diseases, and microbiology of food, milk, water, sewage and soil. There is an appendix classifying the Schizomycetes. There are also a useful glossary and several pages of references. There is much information contained in this book, but it is an unusual type of textbook in some respects. For example, the chapter on tuberculosis contains only one illustration, which is a rather poor reproduction of experimental tuberculosis of the spleen and liver of monkeys. There is no picture of the tubercle bacillus. Since this is a book on microbiology, one would expect the emphasis to be more on the bacteria themselves rather than on the diseases which they cause. In the way of minor criticism, the reviewer feels that it is a waste of ink to entitle the first chapter 'By Way of Introduction' instead of plain 'Introduction.' Selective pruning and reemphasis in future editions should do much to improve this book.

The Principles and Practice of Medicine Designed for the Use of Practitioners and Students of Medicine. Originally written by Sir William Osler M.D. F.R.C.P. By Henry A. Christian M.D. LL.D. Visiting Physician, Beth Israel Hospital, Boston. Fourteenth edition. Cloth. Price \$9.50. Pp. 1475 with Illustrations. New York & London: D. Appleton-Century Company, Inc. 1942.

Fifty years have passed since the publication of the first edition of this famous textbook. Its popularity at one time was such that it led all other textbooks on the practice of medicine in total sales. Since the death of Sir William Osler there has been a succession of rewriters and editors. The present edition has been completely rewritten and reedited, and the text has been changed to fit recent advances in medicine. Much of the material has been rearranged, and new material has been added, according to Dr. Christian, only after experience has indicated that it is worth while.

The present volume begins interestingly enough, with a discussion of psychosomatic medicine, emphasizing the great importance of this new point of view in medical practice. In order to emphasize this still further, the first section of the book is devoted to functional diseases of the nervous system, recognizing those conditions that are essentially nonorganic in nature at least as far as we now know. Here are considerations

of phobias and, incidentally, the use of the term neurasthema as the preferred term for most of the disorders of this type. Strangely, however, the word psychoanalysis is not found in the index nor is there anywhere in this section of the book a specific reference to the Freudian methods. Such methods are introduced in the discussion of hysteria with the recommendation that they be left to those who are especially trained in the field. The consideration of the infectious diseases begins with the pneumonias, and typhoid is now relegated to a place far along the list. However, the outline for typhoid may still serve as the ideal form for the discussion of any infectious disease. One finds the discussion of the common cold under the heading coryza definitely assigned to conditions due to viruses. The consideration of infantile paralysis is condensed and quite up to date. Particularly commendable in this edition are the excellent bibliographies presented in the most modern form, indicating the inclusion of important material practically up to the date of publication.

The literary style makes this book one of the most easily readable of all textbooks on the practice of medicine. The present edition may be highly commended as a great advance over the previous edition and one especially suited to the general practitioner.

A Short History of Cardiology By James B. Herrick. Cloth. Price \$3.50. Pp. 258, with 48 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1942.

History in medicine, as in every other field of human activity, may be said to be composed of the lives of the men who have made history. Guided by this aphorism Dr. Herrick has prepared a history of cardiology based on the lives of the greatest contributors to the study of the heart and of its changes. For Dr. Herrick literature and the history of medicine have been enjoyable avocations. This enjoyment is reflected in the book, which is not a series of biographic sketches, such as one might find in a cardiology "Who's Who," but a well-written consideration of the contribution of each of the great investigators whose work is included with from time to time philosophical and animate versions. For instance, "It is true that Bouillaud had his shortcomings. One may shudder at his wholesale bleedings, one may smile at his rancorous criticism of others, one may regret his waste of time and energy in trivial contentions for the rather empty glory of priority. Overlooking these minor shortcomings, one must honor him for his persistent contention that his views were novel, sound and fundamentally of great importance." Again, "The term 'chronic myocarditis' crept into the literature and was in some respects far from clarifying because it was often applied to processes that were not inflammatory." The book is printed on a special stock, illustrated with portraits carefully chosen, and is worthy of a place in every medical library.

Psychodiagnostics: A Diagnostic Test Based on Perception By Hermann Rorschach, including Rorschach's Paper, "The Application of the Form Interpretation Test" (Published posthumously by Dr. Emil Oberholzer). Translation and English edition by Paul Lemkau, M.D. The Henry Phipps Psychiatric Clinic, Baltimore, and Bernard Kronenberg, M.D., Editor, W. Morgenthaler, M.D. Second edition. Cloth. Price \$5.75. Pp. 226. New York: Grune & Stratton, Inc.; Berne: Verlag Hans Huber, 1942.

This work represents the second edition of the English translation of Rorschach's original papers by Drs. Bernard Kronenberg and Paul Lemkau. As the translators state in their preface, there is a fast-growing interest in the Rorschach test and a need for more information concerning the original and basic work. The translators found the task of adequate translation exceedingly difficult, but it would appear that they have done an excellent piece of work.

The Rorschach test was devised and organized by Herman Rorschach, who was born in Zurich, Switzerland, in 1884 and died in 1922. His early death was a great loss to psychiatry in general and to Swiss psychiatry in particular. He was an extremely versatile man with a sound character and a practical grasp of scientific knowledge together with an inexhaustible interest in research. The Rorschach test, often referred to as the "ink blot test," is being used more and more for the differential diagnosis of personality problems. When given and evaluated by one who possesses a thorough knowledge of Rorschach's method and technique, it offers an excellent guide

relative to the prognosis and choice of treatment to be employed when some form of psychotherapy is indicated. The translation is intended primarily for students of the Rorschach technique, but the book should prove of interest to all students of human behavior. Any comprehensive discussion of the method itself or the evaluations and interpretations placed on the material collected when an individual is exposed to the Rorschach test is not practical if not quite impossible in a short review. Any one who is at all interested in attempts to measure or evaluate problems of human personality structure by means of academic laboratory methods is advised to study Rorschach's basic work very carefully. They seem to offer greater possibilities for accurate evaluation than any other method or methods that have been presented up to the present time. Improvements in the technique itself and evaluation of the material collected are constantly being worked out by Rorschach's followers.

Anatomy of the Human Body By Henry Gray, F.R.S. Edited by Warren H. Lewis, B.S., M.D. Twenty-fourth edition. Cloth. Price \$12. Pp. 1,428, with 1,256 illustrations. Philadelphia: Lea & Febiger, 1942.

A new departure in the twenty-fourth edition of this famous book is the addition to the editorial staff of six distinguished anatomists, who have assisted the editor in revising, rewriting, and making additions of the latest information in their fields, yet the book has retained the familiar arrangement of chapters which has characterized it for many years. The six associate editors are Earl T. Engle, professor of anatomy, Columbia University College of Physicians and Surgeons, New York; Joseph C. Hinsey, professor of anatomy, Cornell University Medical College, New York; Normand L. Houder, professor of anatomy, Western Reserve University, Cleveland; Karl E. Mason, professor of anatomy, University of Rochester, Rochester, N. Y.; David M. Rioch, professor of neurology, Washington University, St. Louis; and Roy G. Williams, associate professor of anatomy, University of Pennsylvania, Philadelphia. Another innovation is the introduction of thirty roentgenograms in the chapter on surface and topographical anatomy, a belated recognition of the important role which roentgenography plays in anatomy. The forty-seven additional pages are accounted for in this way, by the introduction of other new illustrations and by the introduction of new text, particularly in the chapter on the central nervous system.

This edition also contains a picture of brief biographic data about Henry Gray, the original author. While still a medical student, Gray was awarded in 1848 a prize by the Royal College of Surgeons in England for an essay on "The Origin, Connections and Distribution of the Nerves to the Human Eye and Its Appendages." In 1852, when only 25 years of age, he was elected a fellow of the Royal Society and the following year was awarded the Astley Cooper Prize for an essay on "The Structure and Use of the Spleen." He had been demonstrator of anatomy, curator of the museum and registrar of anatomy at St. George's University in London and was a candidate for the position of assistant surgeon, when he contracted smallpox and died at the early age of 34. Henry Gray published the first edition of his anatomy in 1858. It contained 750 pages and 363 illustrations which had been drawn by H. Vandyske Carter, a good friend and demonstrator of anatomy at St. George's Hospital. These illustrations in no small part accounted for the success of the book from the start. A second edition was prepared by Gray two years later.

Psychotherapy in Medical Practice By Maurice Levine, M.D., Attending Psychiatrist, Cincinnati General Hospital. Cincinnati. Cloth. Price \$3.50. Pp. 320. New York: Macmillan Company, 1942.

To attempt to evaluate psychotherapy and to present to the general medical practitioner the essence of psychotherapeutic concepts as a growing and dynamic part of psychiatry is by no means easy. Concreteness, simplification, the removal of the redundant and the elaboration of the complex material of psychoanalysis in terms that can be understood and used by the average medical man is the aim of the author of this book. In large measure he has succeeded, but the size of his canvas tends to distract from the focal point, and details creep in only to confuse and not to clarify. Few men have time or energy, unfortunately, to visualize so vast and all-embracing a picture and yet, given prolonged study, this work will repay

the effort used. The opening chapters on such subjects as common misconceptions, methods for the general practitioner and suicide risks are particularly valuable. Those on sex and marriage and on normality and maturity toward the end of the book seem to be less useful, although most of the material presented is sound. References to the current literature are given and there is a good index. Case histories have been omitted, the author believing that most physicians would skip over them. Doctors as a rule are brought up on case histories and, in the opinion of the reviewer, a few pertinent ones showing end results, with less academic discussion would enhance the value of the book and enable the author to make his points in a more succinct and penetrating manner.

El diagnóstico de los tumores suprarrenales. Por el Dr. Octavio M. Pico. Estrada, profesor adjunto de la Facultad de medicina. Buenos Aires. Paper. Pp. 156 with 1 illustration. Buenos Aires. Librería y Editorial El Ateneo, 1910.

In this special work the author encompasses the subject of diagnosis of adrenal tumors. He points out the local symptoms that adrenal neoplasms produce and their roentgenologic peculiarities. Hypertensive syndromes, the adrenal-genital symptom complexes and the syndrome known as Addison's disease as well as the rare forms of clinical entities accompanied by fever are thoroughly described and evaluated. In chapter IV the author discusses the relationship between the clinical syndromes enumerated and the histologic structure of the tumor formations. Dr. Pico concludes that the extraordinary varieties of the symptoms produced may lead to confusion also that the embryologic ductility and histology of the adrenal may eventuate in multiple varieties of blastoma. The clinical polymorphism here is noteworthy, therefore, for purposes of orientation and in order to enable one to make a correct diagnosis methodic procedure is essential. This can be accomplished only by a thorough study of the symptomatology of the syndromes enumerated. The author intentionally omitted etiologic, physiopathologic and therapeutic consideration. His objective was to stress diagnosis. In other words, a guide for proper recognition of neoplasms of the adrenal is offered. It is a good book, and it welds an additional link in the chain of these often confusing clinical entities. It is written in Spanish.

Ophthalmology and Otolaryngology. Prepared and edited by the Subcommittees on Ophthalmology and Otolaryngology of the Committee on Surgery of the Division of Medical Sciences of the National Research Council. Ophthalmology. Prepared and edited by the Subcommittee on Ophthalmology. Harry S. Gradle, Chairman. Otolaryngology. Prepared and edited by the Subcommittee on Otolaryngology. Harris P. Mosher, Chairman. Volume II. Military Surgical Manuals. Cloth. Price \$1. Pp. 331 with 124 illustrations. Philadelphia & London. W. B. Saunders Company. 1942.

This military surgical manual is divided into two parts, ophthalmology and otolaryngology. It is written mainly for the surgeon and internist who may be called on in military practice to treat injuries and diseases of the eye, ear, nose and throat and is not intended to be primarily a textbook for the specialist.

The section on ophthalmology consists of one hundred and fifty-seven pages and seventy-three illustrations written by seven contributors, each of national prominence. There are eight chapters, which include functional testing and examination of the eyes, injuries, local anesthesia about the orbit, medical treatment and surgical procedures. The text is well illustrated, clear, concise and to the point. The various necessary procedures are outlined step by step.

The section on otolaryngology consists of one hundred and forty-two pages and fifty-one illustrations. There are twelve chapters contributed by sixteen authors, devoted to the various medical and surgical phases of the ear, nose and throat. Considerable space is devoted to primary treatment of gunshot wounds of the face, a topic of vital importance. As in the previous section, the text is brief and to the point. However, there could be more illustrations, which would be of inestimable value to the general practitioner.

The book as a whole is easily readable and is a definite improvement over the manual issued in 1917 during the first world war, which was much too brief. The new manual should be required reading for every doctor in the medical corps.

Essentials of Pathology. By Lawrence W. Smith, M.D., Professor of Pathology, Temple University School of Medicine, Philadelphia, and Edwin S. Cault, M.D., Associate Professor of Pathology, Temple University School of Medicine. With a foreword by James Ewing, M.D. Second edition. Fabrikoid. Price \$10. Pp. 904 with 679 illustrations including 13 color plates. New York & London. D. Appleton-Century Company, Inc. 1912.

Concerning the former edition of "Essentials of Pathology," the authors state in the preface "The most universal criticism which was registered related to the brevity of the chapters devoted to the consideration of general pathology, the material being almost exclusively morphologic." This defect has been corrected by rewriting the first thirteen chapters with addition of approximately 30 per cent of new material. The remaining fifty-five chapters, the case histories and illustrations are practically unchanged. Fifteen pages of bibliography are included in this second edition. These references have been carefully chosen and appear to be quite adequate for the beginning student.

The main features distinguishing this textbook from others is the use of 295 carefully selected case histories with autopsy data to illustrate the dynamics of disease processes. In most instances photographs selected from presented cases are included. Approximately 25 per cent of the book is devoted to general pathology, 20 per cent to oncology and 55 per cent to systemic pathology.

The authors have done an excellent job in correlating embryology, physiology, biochemistry and bacteriology with the study of disease. Considerable attention is given to such topics as vitamin deficiency, virus infection, dental caries, arthritis, shock and other important conditions which are often minimized in textbooks of pathology. The section on parasitic diseases is excellent and quite comprehensive. This is particularly apt at the present time, when tropical medicine is becoming of increasing practical importance.

In general the material is fairly well balanced. There is some disproportion, however, e.g., twenty-one and one-half pages are devoted to diseases of the thyroid gland and less than one page to diseases of lymph nodes. Concerning lobar pneumonia, some might question the "lymphatic method of distribution" of organisms in view of the recent work of Robertson and his associates. The authors' description of the initial tuberculous lesion is not in accord with the general view. Obstructive nephropathy is given scant attention; no mention is made of tubular obstruction by precipitated sulfonamide compounds. It is unfortunate that a book such as this, which should be used a great deal, is too large to fit on a standard book shelf; it measures 11½ by 9¼ inches.

With some discount for case histories, the book contains approximately 10 per cent more words than the average of three leading textbooks of pathology, more than any one of them. This material is well indexed. It is profusely illustrated with excellent photographs and contains thirteen full page color plates. The colored reproductions of various blood elements are especially praiseworthy. In the opinion of the reviewer this is not only an excellent laboratory manual but a good general textbook which adequately presents the essentials of pathology.

Diseases of Metabolism. Detailed Methods of Diagnosis and Treatment. A Text for the Practitioner. Edited by Garfield G. Duncan, M.D., Chief of Medical Service, B. Pennsylvania Hospital, Philadelphia. Cloth. Price \$12. Pp. 985 with 153 illustrations. Philadelphia & London. W. B. Saunders Company. 1942.

This volume achieves its avowed purpose, as indicated by the title, to a commendable degree. It is partly because of the lack of such textbooks as this that the subject is often considered to be difficult by the average practitioner. However, difficult or not, our expanding knowledge of the subject has shown that it vitally concerns a large proportion of the patients who present themselves for treatment. It is therefore incumbent on all physicians to keep abreast of it. In accordance with the recent trend, fifteen different contributors, most of them noted for their achievements in their special fields of interest, have participated in this work. C. N. H. Long describes carbohydrate metabolism, Abraham White protein metabolism and lipid metabolism, Abraham Cantarow mineral metabolism, John P. Peters water balance in health and in disease, Leandro M. Tocantins the nutritional and metabolic aspects of disorders of the blood, Toin D. Spies and Hugh R.

Butt vitamins and avitaminoses, L H Newburgh undernutrition, Frank A Evans obesity, Edward Mason xanthomatoses glycogen disease and disturbances of intermediary metabolism Walter Bauer and Friedrich Klemperer gout, Garfield G Duncan hyperinsulinism, diabetes insipidus and diabetes mellitus, and Abraham Cantarow melituria

As in all such assemblages, there is some unevenness in quality from chapter to chapter. But it is fair to say that the average is high. About two hundred pages are devoted to diabetes mellitus. The large chapter on vitamins and avitaminoses is very timely and ably done. The chapter on obesity is particularly good.

The Sulfonamide Compounds in the Treatment of Infections By Maurice A Schnitker MD Attending Physician Toledo Hospital Toledo Edited by Henry A Christian AM MD LLD [Reprinted from Oxford Loose Leaf Medicine with the same Page Numbers as in that Work] Cloth Price \$2 Pp 25 195 New York Toronto & London Oxford University Press 1942

This book, which is reprinted from Oxford Loose Leaf Medicine with the same page numbers as in that work, represents an attempt to present a reasonably brief but also complete review of present knowledge of the sulfonamides. The contents include an introduction and discussions of the history, chemistry, assay and pharmacology of these compounds. Under separate chapters are presentations of the methods of administration and dosage, clinical uses, toxic effects and their treatment, of sulfanilamide, sulfapyridine, sulfathiazole, sulfadiazine and sulfaguandine. Other chapters offer brief reviews on chemotherapeutic agents such as prontosil, neoprontosil, sulfanyl-sulfanilamide, sulfanyl monomethyl-sulfanilamide, sulfanyldimethyl-sulfanilamide, benzyl-sulfanilamide, sulfa methylthiazole sulfacetamide and promin. A review is also included on the local use of the sulfonamide compounds as well as on their prophylactic use. As a source of information on the chemical and pharmacologic background, therapeutic efficacy and toxicity of the sulfonamides, this book is sufficiently complete and accurate to satisfy the harassed student, the busy practitioner and the hurrying lecturer. Obviously it cannot be expected to meet the needs of the researchist.

Atlas of Otolaryngic Pathology Prepared at the Army Medical Museum Office of the Surgeon General U S Army Largely from Material in the Registry of Otolaryngic Pathology By J E Ash Col Medical Corps U S Army, J L Bernier Capt D C and Roy M Reeve Third edition Paper Price \$5 Pp 176 with illustrations Omaha American Academy of Ophthalmology and Otolaryngology 1942

Col J M Ash, curator of the Army Medical Museum and its extensive registries of pathology, has now enlarged and elaborated the original photographic atlas of gross and microscopic pathology of the nose, throat and ear which was issued in 1939 and thereafter through the provision of funds by the American Academy of Ophthalmology and Otolaryngology. These excellent reproductions of typical photomicrographs, with accompanying text, have become an integral part of the prescribed reading course for residents in otolaryngology which has for several years been a valuable contribution by the academy to training in the specialty and in preparation for examination by the Board of Otolaryngology. Several new subjects have been covered in this edition, notably lesions of the jaws, mouth, external ear and nose. Colonel Ash and his staff deserve great credit for the completion of this highly technical task in the face of personnel and supply difficulties incidental to war conditions. Not a substitute for study of microscopic sections, this fine compilation is nevertheless of continuing value to the average practitioner of otolaryngology as well as to the beginner and the student.

War and the Doctor: Essays on the Immediate Treatment of War Wounds Edited by J M Mackintosh MD Chief Medical Officer of the Department of Health for Scotland Cloth Price \$2 Pp 135 Baltimore William Wood & Company [1942]

The essays in this book are based on a series of lectures delivered to the Edinburgh Branch of the British Medical Association. They emphasize such aspects of war as the neuroses, shock and hemorrhage wounds, first aid instruction and emergency surgery in the field. Each of the essays is written by an author who has had personal experience in the field concerned.

First Aid Surgical and Medical By Warren H Cole MD FACS Professor and Head of the Department of Surgery University of Illinois College of Medicine Chicago and Charles B Puestow BS MS MD Associate Professor of Surgery University of Illinois College of Medicine Fabrikoid Price \$3 Pp 351 with 92 illustrations by Carl Linden in collaboration with Tom Jones of the Illustration Studios of the University of Illinois College of Medicine New York & London D Appleton Century Company Incorporated 1942

This volume is planned primarily for the medical student and practitioner who finds today that first aid is one of his greatest concerns. The book gives special consideration to emergencies related to the war, but it is realized that first aid is equally if not more important in civilian life and in industry. The volume is not the work of a single author, each of the chapters concerned is by a physician who has given special consideration to the problems. For example, injuries to the large blood vessels are discussed by de Takats, medical emergencies by Robert W Keeton, gas and bomb raids by Major Harold C Lueth, injuries of the scalp and skull by Eric Oldberg. The opening chapter on precautions and limitations in first aid work is obviously one of the most important and is accordingly emphasized by the type used. Throughout the book the discussions are practical, the illustrations carefully designed to supplement the text, the consideration succinct and well organized. The book can be highly recommended as a direct, authoritative presentation of a problem immediately important. No doubt much of the advice here contained is likely to be utilized in revisions of the Red Cross manual which certainly at this time requires editing to bring it up to modern points of view.

Cabot and Adams Physical Diagnosis Thirteenth edition By F Dennette Adams MD Instructor in Medicine Harvard Medical School Courses for Graduates Boston Cloth Price \$5 Pp 888 with 398 illustrations Baltimore William Wood & Company 1942

This represents a thorough revision of the previous edition, with many changes and new illustrations which serve to keep the textbook fresh and up to date. The book is comprehensive but maintains its convenient size by conciseness and terse, vivid descriptions amplified by illustrations. One of the peculiar features of the book, which has enabled it to maintain a position of leadership through thirteen editions and forty years, is the interesting manner in which it relates signs and symptoms to the various clinical entities. The salient features of the various syndromes and diseases are selected with obvious care and discrimination without in any way neglecting descriptions of signs and symptoms and the technique of eliciting them. This textbook is recommended not only for medical students but for those clinicians who wish to have a ready reference work at their disposal.

American Jewish Physicians of Note: Biographical Sketches By Solomon R Kagan MD Cloth Price \$5 Pp 304 with 129 illustrations Boston Boston Medical Publishing Company 1942

This volume is intended to supplement previous editions which present biographic sketches of Jewish physicians, including those who have attained eminence as investigators, teachers or leaders. The volume makes no pretense at completeness but is exceedingly useful for the material that it offers. The sketches seem to have been arranged in the book largely at random. The book includes also a chronology of important discoveries.

Visual Aids in Safety Education Supplement I Prepared by the Safety Education Projects of the Research Division Paper Price 25 cents Pp 59 Washington D C National Education Association of the United States 1942

The Safety Education Projects of the Research Division of the National Education Association has prepared this supplement to a previous publication with the same name published two years ago. All films have been previewed by members of the committee with special attention to objectionable advertising, failure to observe modern teaching methods, inexperienced acting and outmoded clothes and automobiles. Two hundred and ninety-nine motion pictures, sound-slide films and film strips are listed, covering all phases of safety education. The old style lantern slide has almost ceased to exist, for only four subjects are mentioned using this method of presentation. The pamphlet also contains the names of 362 distributors of safety films and slides and 61 distributors of safety posters. It should prove useful to persons interested in safety education.

Queries and Minor Notes

THE ANSWERS HERE FURNISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

INTRACRANIAL HEMORRHAGE OF NEWBORN

To the Editor—What is the current status of handling intracranial hemorrhage of the newborn, any type early or the type that shows itself twenty-four or seventy-two hours after birth? I am particularly interested in spinal puncture, is it used at all or is it done repeatedly? Are there any advocates of intravenous hypertonic solutions? In your answer please disregard reference to vitamin K and other preventive measures.

William H. Dixon, M.D., Rocky Mount, N.C.

ANSWER—The management of intracranial hemorrhage of the newborn should consist in keeping the infant as quiet as possible, consequently, energetic treatment should be avoided. The head of the crib should be elevated to reduce cerebral venous pressure. Phenobarbital in small doses may be administered for relief of convulsions or extreme restlessness.

There is a great difference of opinion about the value of lumbar puncture in these cases. If the fontanel is bulging and a pronounced increase of intracranial pressure is suspected lumbar puncture will probably be made, though when the hemorrhage has been diffuse and oozing, continuous the withdrawal of fluid gives only temporary relief. If subdural bleeding can be recognized, a puncture may be made at the lateral angle of the fontanel.

In the literature there are a number of references to surgical intervention. Most neurosurgeons show considerable skepticism about operation. In newborn and young infants the hazard of brain operation is serious, most of the patients succumb to shock. The number of successful results is small. Certainly intratentorial hemorrhages are not amenable to operative treatment. Even when the hemorrhage is supratentorial, operation should not be undertaken lightly.

It is not usually considered advisable to operate until the third or fourth day after birth. Even if the blood clots are removed it is still doubtful if complete recovery will ensue because of the damage which already has been done to the underlying brain tissue. Moncrieff (Alan Brit Med J 1:1068 [June 16] 1934) recommended the infusion of hypertonic dextrose solutions in cases of commotio cerebri. The same author also recommends that enemas of 60 or 90 cm of 10 per cent salt solution should be given every four hours in the hope that brain pressure may be relieved.

CAPILLARY FRAGILITY AND HEMORRHAGE DURING MENSTRUATION

To the Editor—A few of our local dentists will not extract a tooth from a menstruating woman because postoperative hemorrhages occur with greater frequency in these cases than otherwise as the result of changes in the blood chemistry at this time. Is there a scientific basis for such a statement or is it merely a coincidence? Any information will be appreciated.

M.D. Pennsylvania

ANSWER—There is some scientific basis for this clinical observation. Brewer (J Am J Obst & Gynec 36:597 [Oct.] 1938) found that in women with normal ovulatory menstruation there are rhythmic changes in the skin capillaries associated with the cyclic menstrual rhythm. These changes are essentially in capillary fragility. During the few days prior to and on the first day of menstruation, capillary hemorrhage is produced with relatively greater ease than during the remainder of the cycle. These rhythmic changes are the direct result of vascular spasm. In functional uterine bleeding, the vascular rhythm in the skin capillaries is profoundly disturbed and is completely dissociated from the menstrual rhythm. These facts indicate that menstruation which is evidenced as a local vascular phenomenon is a part of a demonstrable generalized vascular phenomenon present in the entire body.

Increased capillary permeability can be demonstrated by the Rumpel-Leede test, which is performed by applying a moderately tight rubber bandage around the upper arm for ten minutes. When it is positive, subcutaneous hemorrhages appear below the bandage. In normal women such petechial spots are readily produced at the time of the menses but rarely in the preovulatory phase.

LOCAL ANESTHESIA AND INTERCOSTAL BLOCK FOR ABDOMINAL WALL

To the Editor—Ogilvie (Surg Gynec & Obst 68:295 [Feb 15] 1939) advises the use of a solution for local anesthesia of the abdominal wall which is composed of procaine hydrochloride 0.5 per cent and quinine and urea hydrochloride 0.25 per cent. What are the advantages and disadvantages of the addition of the quinine and urea hydrochloride to a local anesthetic solution? Ogilvie advocates a technic of abdominal wall block by infiltration of the lateral borders of the rectus sheath. In the same journal (71:194 [Aug.] 1940) Bartlett advocates intercostal nerve block beneath the lower six ribs in the midaxillary line bilaterally for anesthesia of the abdominal wall above a level 2 inches below the umbilicus. What are the relative advantages and disadvantages of these two methods of anesthesia of the upper abdominal wall? M.D. Alaska

ANSWER—The advantage of adding quinine and urea hydrochloride to a local anesthetic solution is that it prolongs the local anesthesia considerably. The disadvantage is that not all persons tolerate the drug, and, in some instances in which it has been used stronger than 0.25 per cent, sloughing has occurred. The advantage of abdominal wall block at the border of the rectus sheath is that anesthesia lasts longer than when intercostal block is done and there is less bleeding when the incision is made. Less general anesthesia is required for the intra-abdominal part of the operation in most cases than if local anesthesia is not used. The advantage of intercostal block advocated by Bartlett is that, in those patients who have abdominal scars and the bowel is adherent to the abdominal wall the abdominal wall block is to be avoided for fear that the bowel might be perforated by the needle in doing the block. The intercostal block produces anesthesia and relaxation of the abdominal wall without injecting into the abdominal wall itself. For the patient who is debilitated so that one must restrict the amount of local anesthetic to be used intercostal block permits more anesthesia with less solution than does abdominal wall block.

INDUSTRIAL POISONING ASSOCIATED WITH DROSSES

To the Editor—I have been observing two men for the past month who work together in a plant that has to do with reclaiming drosses. Both men have mild symptoms of multiple transient joint pains and neuritic pains. Recently they have been complaining of a bad taste in the mouth and bleeding of gums when brushing their teeth. Mild general malaise and slight anorexia. All symptoms are moderate and at present more annoying than anything else. Examination is entirely negative except for a slight drop in hemoglobin and red cell count. The metals and gases that they came in contact with are tellurium, chlorine, sulfur and antimony. For the most part they use protection whenever they think it advisable. If you have any information on these metals and gases I would appreciate your sending it to me or telling me where I might be able to read up on them.

R. D. Campbell, M.D., Cleveland

ANSWER—Drosses, skimmings and slags resulting from molten metal operations sometimes provide highly difficult problems in industrial toxicology. Most metals are impure, and the quantity of impurities often is appreciable even in drosses. Lead, arsenic and zinc are common impurities for many metals. In a metal dross recovery plant the type and quantity of impurities may vary almost daily. Only the unwary would commit himself to any specific exposure in general metal dross recovery work. Granting that some injury of occupational disease nature may arise under such circumstances as described, it is appropriate to contemplate mixed or combined causes. This is no new concept of occupational disease etiology, having been sponsored years ago by Hayhurst and other physicians. Naturally any disease state from mixed causes may present such bizarre manifestations as to defy classification. The symptoms mentioned suggest antimony poisoning but there have been few cases of reported antimony poisoning in this country to furnish the manifestations of the antimony syndrome. For practical purposes this dross recovery work should be well ventilated to the end that all gases and fumes shall be discharged to harmless points. The intermittent, haphazard wearing of respirators is not sufficient. Should the severity of the infirmities of these workers increase appropriate laboratory examination of urine, feces and blood should be made for specific materials such as lead, arsenic, antimony, tellurium and selenium. In antimony poisoning a high eosinophilia is believed to occur. In lead poisoning repeated quantitative lead in urine determinations should be made. On the assumption that antimony might be the chief offender, a number of references are given.

UNUSUAL LARYNGITIS AND CHONDRITIS

To the Editor—Eighteen months ago a woman aged 27 had an acute infection of the left side of the larynx. This began as a small ulcer and then rapidly became a widespread necrosis. The Wassermann reaction was negative. Bacteriologic studies showed a number of organisms, mainly streptococci of nonhemolytic variety and many Vincent's organisms both spirochetes and bacilli. It involved the posterior region including the interarytenoid region. Healing was rapid with neosphenamine sodium perborate and powdered methylene blue but every few months there would be a recurrence with great suddenness—so suddenly that the last time I looked at her larynx in the morning there were no symptoms and yet that night there was a full blown ulceration with edema, foul discharge and what looked to me to be at least a partial separation of the processus vocalis. The best description I can give is that it reminded me of cancer of the oral cavity on a mild and localized scale. The fear that another upset would permanently injure her voice led me to ask a competent radiologist if irradiation would help. He gave five daily treatments the various factors of which I do not know. It healed well and has not recurred in a year's time. However, about a month later both cords got hyperemic and while this condition has lessened the attached margins have a dusky cyanotic redness. The destruction has been repaired with the possible exception that the transverse arytenoid muscle does not quite fully approximate the posterior ends of the cords. The patient can talk although in a few moments her voice plays out. Is there anything that can be done for the radiation erythema? I am sure this is due to the radiation for the right cord never was involved in the process of infection and is less inflamed than the other cord which was nearer the tube.

M. D., Arkansas

ANSWER—While the cause of the original infection is not known the subsequent changes were due to a chondritis of the arytenoid cartilage with probably some involvement of the signet of the cricoid. The frequent recurrences with edema and purulent discharge suggest that small sequestrums of cartilage were discharged at irregular intervals. Irradiation probably aided in securing more prompt resolution.

Five roentgen treatments should not produce a severe erythema unless the dosage was larger than commonly employed. It would seem that the persistence of a low grade infection would be a likely explanation in spite of the fact that there has been no recurrence of severe symptoms for about one year. If it is due to irradiation there is relatively little to be done although some patients secure relief by the employment of a bland medicated oil, preferably mentholated, a vegetable oil base being used, which may be instilled into the larynx or introduced with an atomizer. The patient can be instructed to use this and can employ it several times daily.

BULLET WOUNDS OF PULMONARY VESSELS AND SPEED OF DEATH

To the Editor—I should like some information as to the occurrence of death from gunshot wounds. A man was shot laterally through the chest from right to left by a 0.25 35 caliber bullet fired from a distance of 12 inches. The bullet passed through a window of a car with shattered proof glass and then passed through the body of the man. In the course through the body the bullet completely severed the pulmonary artery just above the heart. The coroner's jury asked me how long the man lived after such a wound. Basing my answer on an electrocardiogram taken a year or two ago in a prison when a man was executed by a firing squad I answered that he probably lived about fifteen seconds. They also asked me if after the bullet passed through his body he would have been able to shut off the switch of his motor or to have opened the car door. My answer was that he could do neither of these. I would also be interested to know whether or not the mechanical force of a bullet this size would have been sufficient to push the man over. Evidence would seem to indicate that at the time the man was shot the car door on his left was open and that the body fell out of the car. He was lying at right angles to the car with his feet near the running board and his head away from it. The body was stretched out lying on its back. Would there have been enough muscular reaction for the body to get in this position or would the supposition be that if it was in this position, it would have had to be placed there by some one else? This shooting occurred as a hunting accident—it is not a medicolegal case. If consistent I should be pleased to have as much information on these matters as possible.

M. A. Shillington M.D., Glendive, Mont.

ANSWER—Bullet wounds of the aorta and pulmonary artery as a general rule are quickly fatal. This is true also of perforations of the innominate artery and the iliac vessels and to a lesser extent of the subclavian and carotid arteries. Gunshot wounds of the cardiac auricles are more rapidly fatal than those of the ventricles, especially the left ventricle because the thick muscular wall may check bleeding by its contraction.

If no communication exists between the pericardium and the pleura, death may occur rapidly by asphyxia from compression of the heart. However, if the blood has an opportunity to leak into one or both pleural cavities, the death may be delayed for several minutes.

Bullet injuries of these structures are not instantly fatal. Victims may live for several minutes, in fact it is recorded that some have walked or run considerable distances and even climbed stairs. Under these circumstances caution must be

exercised in expressing an opinion whether a person shot through the pulmonary artery could or could not turn off the ignition or open the door of a car before collapsing.

Ordinarily the sequence of the rapidity of a fatal issue following gunshot wounds is as follows: the aorta, main pulmonary artery and cardiac auricles, the ventricles, the iliacs and innominate artery, the femorals, subclavians and carotid arteries.

In wounds through the large veins, namely the cavae, iliacs and so on, the time interval between the receipt of the injury and death may be longer, in comparison to wounds of the corresponding arteries. Each case must be judged individually.

HORNER'S SYNDROME

To the Editor—Are there two kinds of Horner's syndromes: (1) paralytic with miosis, enophthalmos, ptosis and anhidrosis and (2) irritative, with mydriasis, exophthalmos and the like? I would appreciate it if you would list references with the reply. Archie Sheinmel M.D., Alexandria, La.

ANSWER—Horner's syndrome or Horner-Bernard syndrome is characterized by miosis, decreased palpebral aperture (pseudoptosis), retraction of the eyeball (enophthalmos), dilatation of the blood vessels, anhidrosis and finally increase of temperature on the face and head. All these symptoms occur on the same side as the lesion. This syndrome was described by Claude Bernard as well as by Horner. Bernard sectioned the sympathetic nerve in the neck and observed the signs mentioned. There is only one kind of Horner's syndrome. That is due to a lesion of the cervical sympathetic resulting in paralysis. Symptoms of irritation of the cervical sympathetic usually precede or occur simultaneously with paralysis. Dorland's Medical Dictionary of 1929, Tilly and Riley second edition, page 356, Wechsler, fourth edition, page 70, Church and Peterson 1909, page 107, Bing and Haymaker fifth edition, page 267, Oppenheim, 1911, volume 2, page 1315, Purves Stewart, eighth edition, page 568, Brock, 1937, page 67, Dana 1915, page 102 and four other textbooks on neurology all agree with the opening statement given.

NERVE SUPPLY OF CERVIX UTERI

To the Editor—Is there any adequate discussion of the nerve innervation of the cervix uteri? In addition I should like a picture or diagram of the nerves if either is available. Harry Anker M.D., Akron, Ohio.

ANSWER—The nerve supply of the uterus comes from both the sympathetic and the cerebrospinal system. The motor fibers are derived from the sympathetic system passing down from the aortic plexus. They are reinforced by fibers from the solar renal and genital ganglions forming a large plexus above the promontory of the sacrum near the bifurcation of the aorta called the great uterine plexus. From here the fibers pass on either side of the rectum through the hypogastric plexuses to the sides of the uterus but mainly to the great cervical ganglion and thus into the uterus. Cerebrospinal fibers come from the pneumogastric, phrenic and splanchnic nerves and follow the same course. The uterus also receives innervation from the lumbosacral autonomic system by way of the pelvic nerve (second, third and fourth sacral) to the uterocervical ganglions.

Sensory fibers come from the spinal cord through the sacral nerve, being also distributed by way of the great cervical ganglion. The latter, or Frankenhauer's ganglion, is a triangular mass of ganglion cells and nerve fibers lying behind and at the side of the cervix and upper vagina.

There is an explanatory diagram in De Lee's Principles and Practice of Obstetrics, seventh edition, Philadelphia W. B. Saunders Company, 1938, page 81.

COLOR BLINDNESS

To the Editor—A soldier aged 22 has lost a number of chances for advancement because of color blindness. Believing color blindness to be congenital I had informed him that there was no treatment for it. He has worked around moving picture projectors and photostatic equipment and believes this work may have had something to do with his condition. He states that some of his comrades with a similar condition have been given treatment by army doctors. He matches yarns correctly but sees the wrong numbers on color plates unless the plate is in a strong natural light and the pages are turned slowly. Is there any known correction for this condition? M. D., New Mexico.

ANSWER—Color blindness is a congenital defect and in the true sense of the term is never acquired. Extrinsic conditions such as those mentioned, have no influence on the color perception, which may vary from complete absence of color recognition to mere inability to differentiate various shades. There is no known correction for this condition despite the claims of some optometrists.

PSYCHOSOMATIC ASPECTS OF HYPERTENSION

EDWARD WEISS, MD

1111 N. Dearborn

It is generally admitted that psychic factors play some part in essential hypertension. Thus, it is always emphasized that we must allow for the emotional element in individual blood pressure readings. It is also well known that rest and reassurance play a large part in the medical management of hypertensive patients both in relief of symptoms and in reduction of the blood pressure level.¹ The early symptoms of hypertension are often exactly those of a psychoneurosis. Emotional stress at times seems to precede the onset of hypertension and anxiety bears a close relationship to the aggravation of existing symptoms in hypertension. Personality study often reveals a deep seated conflict which stands in close relationship to this anxiety.²

To study these and related problems I have reviewed the records of 200 consecutive patients with the symptom of hypertension, of whom 144 seemed to correspond to the clinical picture of so-called essential hypertension. Of these 93 permitted satisfactory psychosomatic study. This included the usual general medical survey, with special emphasis on the cardiovascular-renal system plus urographic studies and observations of renal blood flow in selected cases, and personality studies which, according to a scheme outlined elsewhere,³ consisted in a detailed investigation of the life situation and of the personality structure, in a series of from two to six hourly interviews.

The following groupings were made. Group 1, 5 cases, were those in which the psychic factors seemed intimately related to the onset of the hypertension and, apparently, an important factor in its development. Group 2, 48 cases, consisted of those instances of hypertension in which psychic factors seemed chiefly responsible for symptoms, even though their relation to the onset could not be determined with any degree of certainty. Group 3, 33 cases, was made up of those in which psychic factors seemed partly responsible for

symptoms and, therefore, important in treatment, and group 4, 7 cases, were those in which psychic factors apparently bore no relationship either to the onset of hypertension or to the production of symptoms.

All varieties of personality type, including psychoneuroses and character disorders, were discovered and of these the compulsive type of character was in the majority, but no significant correlation between group and personality type could be established.

PSYCHOSOMATIC ASPECTS OF ETIOLOGY AND PATHOGENESIS

Two psychic tendencies seem to stand in close relationship to hypertension—anxiety and rage. Essential hypertension is one of the commonest disorders of civilized life, and anxiety states are certainly no less common, therefore, simply from the standpoint of their frequency, it is not surprising that the two are often present in the same individual. But the question which interests us is this: Is there a more specific relationship between the two?

It has long been known that anger is an emotion connected with high blood pressure, how often people remark to a person who is angry "Now watch your blood pressure." However, psychoanalytic studies suggest that hostile impulses of which neither the individual nor the casual observer is aware may also have an important influence on the blood pressure. In other words, long-continued, repressed rage may manifest itself through the circulatory system by elevation of the blood pressure. Alexander,⁴ Saul⁵ and Dunbar⁶ all call attention to the unresolved psychologic conflicts which give rise to chronic emotional tensions, and these, they feel, are specifically related to the hypertension.

The factor of repressed rage is seen in the following case of early essential hypertension from group 1.

CASE 1³—Recurrent attacks of acute psychosomatic hypertension with hypertensive encephalopathy. Apparently no harm from excessive energy output when directed along aggressive channels, recurrence of hypertension corresponds with period of thwarted aggression.

History—A white man aged 29 was first referred to the Temple University Hospital in December 1935 with the diagnosis of acute appendicitis which was proved at operation. The blood pressure during spinal anesthesia gradually fell from 140/78 to 86/48. The patient later reported that he had been "scared to death of the operation" that he knew it was a "pus appendix" and that he was fearful that peritonitis would develop. Ten days postoperatively a note on his record stated that he seemed somewhat hysterical. The blood pressure had been normal and the general physical condition seemed satisfactory, so that he was discharged at the end of two weeks.

From the Department of Medicine Temple University School of Medicine.

⁷ Dunbar C. Clusters, Character and Symptom Formation. *Psychosom Med* 1: 187 (Jan) 1939.

The same evening he felt dizzy, became delirious and had to be restrained. The following morning he reported "that he was blind in both eyes." He was sent to the psychopathic ward of another hospital where he remained for three weeks. From its records it was noted that he had reported that when he came home from the Temple University Hospital he developed pain in the suprapubic region which extended into the testicles, which was terrible. "It made me almost hysterical." He woke up unable to see and became very agitated. At the hospital he had auditory and visual hallucinations. On discharge he was so weak that he was unable to walk. Because of this weakness and nervousness he was readmitted to Temple University Hospital in February 1936.

Physical Examination—Emaciation was pronounced. The skin was warm and moist. There was considerable muscle weakness and muscle twitchings were quite evident. The blood pressure during this stay in the hospital varied between 160-180 systolic and 110-120 diastolic. There was no evidence of thyroid enlargement. The heart seemed normal in size, the aortic second sound was accentuated. The eyeground examination showed evidence of an acute vasospastic retinitis without organic sclerosis (Dr. Gibson). The nasal retinal arteries were especially constricted. The temporals showed moderate attenuation. There were a few hemorrhages and exudates in the right retina and many in the left. The spinal fluid examination showed an initial pressure of 10 mm of mercury. The fluid was clear, and no abnormalities were detected. Psychiatric examination found the patient well oriented and suggested that he had previously suffered from an organic delirium.

The urine examination showed no albumin, although there were occasional casts. Renal function was normal. The blood count showed a moderate degree of secondary anemia. All blood chemical studies, including dextrose tolerance, were within normal limits and the basal metabolism was plus 6 per cent.

Previous Medical History—This was negative except that since about the age of 16 he had a 'bilious headache' about once a month unless he 'warded it off' with a laxative. He reported that his father had suffered from the same kind of headache.

He completed the eighth grade of school. He married at the age of 20. His wife had two children, one of whom died in infancy and the other was living and well.

His father suffered from valvular heart disease and his paternal grandfather died of a 'stroke' after the age of 60. The mother had gallbladder disease, and the maternal grandfather died of uremia. The patient was the oldest of a family of six, and there was nothing remarkable in the medical history of his brothers and sisters. None of them had hypertension.

After his discharge from the hospital he was carefully followed by his physician, who recorded that the blood pressure gradually fell from 150/110 to 130/88. This last reading was obtained after the patient had returned to his job as truck driver in a large concern and had been working for about a month. Meanwhile his weight had increased from 114 to 127½ pounds (from 52 to 58 Kg) and he felt very well.

Third Hospital Admission—In May 1936 he witnessed an automobile accident and, although no one was injured, the patient became terribly excited over what might have happened to some children who were playing in the path of the truck. He 'knew that he would get sick again' and after a few hours of restless sleep he awakened with abdominal pains, nausea, vomiting and diarrhea. (Later his physician reported that the first illness, that is, the appendicitis, had begun similarly 'like gastroenteritis with diarrhea'. Nausea and vomiting continued and also the diarrhea. Sleep was restless and fitful and a few days later the patient reported blindness on awakening but there was no evidence of this when examined by his physician later in the day. Abdominal examination was negative but the blood pressure was now 160/100. That night he had convulsive seizures. By midnight he was mentally clear but the blood pressure was 190/110. He was readmitted to the Temple University Hospital in June 1936.

On this admission the blood pressure remained constantly at 200-210 systolic and 140-160 diastolic. There were almost no fluctuations. Even during sleep the blood pressure on several

occasions was found to be 175/125. Weakness was not so pronounced as before. Now the eyeground picture was stated to be acute vasospastic retinitis with arteriosclerosis grade 1 but the functional (spastic) element was still the predominant feature. There were some retinal scars where previous exudates had been.

Psychologically it was found that the patient had been sleepless and restless ever since witnessing the accident, whereas previously he had always been an excellent sleeper. He kept recalling the accident and thought how "terrible" the consequence might have been. Dr. English suggested that there had been a great deal of unconscious anxiety, which, following operation, had resulted in a psychosis but had then subsided during which time the patient improved and remained well for more than a month. Then after the accident anxiety broke out again, not quite to the former extent but with pronounced insomnia and a constant feeling of tension.

Following discharge from the hospital in June 1936 the patient constantly improved. The weight increased and the blood pressure gradually diminished. During the latter part of June it was reported on several occasions at 140-150 systolic and 110-120 diastolic. By the latter part of July the blood pressure had dropped to 120/90. The weight had increased to 121½ pounds (55 Kg). The patient felt perfectly well, eating and sleeping normally, and once more returned to work.

During this period more detailed information bearing on his life situation was obtained.

Life Situation—According to the mother the patient was a normal child, the oldest of six children. Other than difficulty in weaning there were no behavior problems although there were occasional nightmares. He began working at the age of 17. For some time he was employed as a clerk with a refining company and there he 'first developed a fear of operations' a friend had the wrong kidney removed. There he also saw many accidents and deaths and it was largely for that reason that he gave up the position. He was always afraid of hospitals 'a fear of being cut'.

He married at the age of 20. Although his wife was frigid he indulged in frequent intercourse and asked whether perhaps that might be responsible for his present difficulties. Occasionally he would suffer from premature ejaculation. With his illness he lost desire for intercourse. Then when desire returned he could not maintain an erection. Since the illness he had developed nocturia. He would awaken with a 'water' erection and complained of a pain in the testes.

For the past eight years he had been employed as a truck driver for a large concern. Beginning in the spring of 1937 he began to interest himself in union work. He stated that his father, who had worked for the same company had always resented the company's 'restrictions' but did nothing but he said 'my mother is a fighter and I must have inherited it from her'. Furthermore, his father was killed by a truck in the summer of 1937, and the company was fighting compensation. This he said 'makes me more determined than ever to fight'. He threw himself into the work with great intensity and after working seven and one half hours a day on the truck he would then engage in union activities for another five or six hours and, in spite of this fact at the end of six months of such constant pressure of activity he had gained weight and his blood pressure still averaged 135/90. He became an official of the union and, in addition to the long hours of work, managed to do a great deal of study. He often worked eighteen out of twenty-four hours and rarely got more than six or six and one half hours in bed. His activity in union work dated from April 1937 to January 1939, his blood pressure was still 135/90 and he enjoyed excellent health.

In October 1936 Dr. Gibson found the eyegrounds almost normal. There was very slight attenuation of the nasal arterioles with arteriosclerosis grade 1 of the hypertensive type in the periphery of all four arterioles and residual scars of previous retinitis.

All vasospastic features had subsided and a remarkable increase in the caliber of all vessels was noted. In July 1939 Dr. Gibson found a very mild attenuation of the arterioles.

without exaggeration of the reflex stripe. The retinitis has completely subsided. This is a most unusual remission in the retinal picture of hypertension."

Recurrence of Hypertension—In September 1939, for the first time since his recovery, the blood pressure was definitely elevated, 160/105. Union activities had 'folded up' in the early part of June, he was bitterly disappointed and was anxious to do something about it but could not stir up any enthusiasm among his associates. When talking to them he got so hot under the collar that he lost the power of speech. He felt very keenly that something should be done but he just couldn't push things through. He had a constant feeling of tension and could not relax. The injustice was burning him up, he felt himself boiling inside and could commit murder."

Coincidentally there had been a recurrence of premature ejaculation and a feeling that he could not be satisfied sexually."

It seemed obvious that his throttled aggression manifested itself both in the sexual sphere and in his general feeling of not being able to relax, of being irritable and easily angered. I suggested that the tension which he formerly got rid of in union activities was now bottled up and had to find an outlet in bodily symptoms.

Summary—A man of 29 with pronounced 'mutilation anxiety,' first seen in December 1935, developed high blood pressure and an acute psychosis following an appendectomy when he became fearful that peritonitis would develop. An acute vasospastic retinitis developed, but the heart and kidneys seemed unaffected. The hypertension gradually subsided, but in the spring of 1936, following an anxiety producing episode, hypertension, vasospastic retinitis and hypertensive encephalopathy again occurred. Once more the blood pressure and eczematoid changes subsided as anxiety was reduced and for the next three years the patient remained well, having maintained a normal blood pressure (135/90) since July 1936.

For almost two years of this period he was well and the blood pressure remained normal in spite of excessive work. The long hours and intense activity were employed, however, in union activities, in which he was able to give direct expression to his aggressive impulses. Union activities ceased in the spring of 1939 and in September he was once more suffering from tense feelings, experiencing sexual difficulties and the blood pressure was once more elevated. This coincided with the period of throttled aggression.

SUMMARY OF PSYCHOLOGIC MATERIAL WITH REGARD TO ETIOLOGY AND PATHOGENESIS

Anxiety and rage are emotional factors commonly related to hypertension. Psychoanalytic observations show that rage is chronic and repressed and that the resulting psychologic conflict produces "tension" that seems related to hypertension. In some patients it is apparently the chief among the multiple factors that enter into the pathogenesis. An analogy might be drawn to the role of the kidney or the endocrine glands, either of which, in rare instances, may be chiefly responsible for the presence of hypertension but in most instances seem to play a secondary role, depending on a constitutional or inherent tendency. The psychologic factor is only one phase, although an important phase, in the 'composite of the degree and kind of renal, endocrine and nervous participation'.⁸ An attempt to demonstrate this relationship is shown in the accompanying diagram. This makes an effort to indicate the relative importance of constitutional and hereditary factors, which make up the base of the pyramid, with regard to the interrelated systems of the body that have to do with hypertension, shown as the sides of the pyramid. These systems are then shown as triangles, with the sides of the triangles representing interrelated factors.

PSYCHOSOMATIC ASPECTS OF THE CLINICAL PICTURE OF HYPERTENSION

Although Ayman² showed that the early symptoms of hypertension are psychoneurotic, it still is common practice to place the blame for all symptoms in a hypertensive individual on his high blood pressure. When the hypertensive-vascular disease is advanced and vital organs have been affected, it is, of course, true that many symptoms are caused by failure of these organs. Even here, however, it is important to evaluate the part played by emotional as well as physical factors.³

In an analysis of symptoms in this series of patients, two special groups occurred with great frequency: (1) headache, dizziness, fatigue and constipation in 50 patients and (2) pain in the heart region associated with palpitation, dyspnea and fatigue in 38 patients. Of course as Ayman² showed, all combinations occur, but these groupings are very common.

Janeway⁹ observed that headache was the most frequent symptom of which his hypertension patients complained. He described the typical hypertensive headache which appears on awakening, consists of sensations ranging from a dull ache to severe pounding

Diagram to summarize discussion of pathogenesis. The base of the pyramid is made up of constitutional and hereditary factors; the sides consist of interrelated systems which are shown separately as triangles with their sides representing interrelated factors. From Weiss, Edward. Recent Advances in Pathogenesis and Treatment of Hypertension—Review. *Psychosom Med* 1:180 (Jan) 1939.

distress and is usually located in the cervico-occipital region. But, in addition, he noted that a surprisingly large number of patients had been subject to migraine throughout life. Gardner, Mountain and Hines¹⁰ found migraine five times as frequently in hypertensive patients as in a control group. Then there are a great variety of head pains, discomforts and peculiar sensations, such as dullness and fulness with or without vertigo, which occur in hypertensive subjects and are often referred to as headaches. The tendency is to attribute all these "headaches" to the hypertension. Certainly elevation of the blood pressure seems responsible for the so-called typical hypertensive headache (even here, the anxiety factor enters as far as it is related to exacerbations of blood pressure), but the vast majority of peculiar head sensations and discomforts often designated as headache cannot be correlated

with the blood pressure level itself. Here the emotional factor is directly related to the peculiar head sensations. An example from group 2 follows.

CASE 2—Hypertension and anxiety: the emotional factor in relation to headache and fatigue

History—A white woman aged 55, first seen in October 1941 complained of hypertension, which had been discovered about a year before headaches and fatigue.

Headaches had occurred for the last few years. They were not typical hypertensive headaches. They were located in the front of the head, were described as a dull ache and were occasionally present in the morning but usually became more severe as the day wore on and 'took the life out of her'. During the same period she found everything to be an effort, had no ambition and tired very easily. Because of headaches and fatigue she had sought medical attention, and then the blood pressure elevation had been discovered.

There was nothing significant about the past medical history. Artificial menopause had been brought about fifteen years before following excessive bleeding.

She had been married for thirty-five years and had one child, now a man of 30 who was well. There was a history of hypertension on the father's side of the family and the father had died of a stroke of apoplexy at the age of 75. The patient thought that she resembled her father.

Physical Examination—The blood pressure averaged 200/120. The heart seemed within normal limits as to size as determined by the orthodiagram and the electrocardiogram indicated only left axis deviation; other features being within the limits of normal. There was no evidence of impairment of cardiac function. The eyegrounds showed arteriosclerosis of the hypertensive type grade 1 but no evidence of retinitis. Urinalysis was negative and renal function as measured by the urea clearance test was within normal limits. An intravenous urogram was normal.

The conclusion was essential hypertension with symptoms out of proportion to disease.

Life Situation—The patient had been 'a healthy, happy child reared in a cultured atmosphere. Following an unhappy love affair she had married a man who turned out to be 'stupid, stingy and stubborn' and who failed to provide for her properly. She had entered business with him, as did the son later, in an effort to provide more successfully for the family and save the expense of hiring help. There was much contention between the passive dependent son and the harsh and critical father. The patient, whose sympathy was with the son, had to act as a buffer between the two. While she was a pleasant and intelligent person she too had a passive personality and dared not fight with her husband who had 'a terrible temper'.

In addition to the difficulties of this situation she had become painfully aware that her husband was engaged in an extramarital affair. Indeed, he made no secret of the fact. He considered this a natural appetite that had to be satisfied whereas smoking and drinking were unnatural appetites that were quite sinful. She was subjected to constant humiliation with regard to this affair but was never able to do more than hope that some day this stubborn and vindictive man would die, so that she might have some peace. The latter information of course was not expressed directly as a wish. It was stated quite indirectly but was an obvious indication of the difficult family situation from which she could not extricate herself and for which she seemed to be paying a price in the symptoms of headache and fatigue. She herself suggested that there was a definite relationship between contention, tension and hypertension.

The opportunity, for the first time, to discuss her situation led immediately to some relief of anxiety and, although no advice was given regarding her family situation, she apparently gained enough courage to confront her husband with an ultimatum regarding his extramarital affair. Contrary to her beliefs, this brought him to his senses and removed one of the tension-producing factors from her environment. At the same time she managed to regulate her life more successfully so that she obtained more physical rest and this in turn seemed to bring about improvement.

After a few weeks blood pressure figures were somewhat lowered, but the chief benefit was the disappearance of symptoms and the improvement in her attitude and general sense of well being.

Summary—A middle aged woman complained of headaches and fatigue and had hypertension. The symptoms seemed out of proportion to the amount of physical disease. She was a passive personality caught in a family situation which produced humiliation and rage from which she could not extricate herself. Airing her problems permitted a better perspective and allowed her to mobilize her aggression along more direct channels. Relief of symptoms followed although the blood pressure was not materially affected.

Migraine presents a more complicated mechanism. It can hardly be assumed as in the case of anxiety and hypertension, that migraine is so frequent in hypertension because the two are common disorders and therefore must frequently meet. Instead there seems to be a common denominator, and psychologic study gives a clue. Apparently there is an intimate relationship between the personality structure of the two disorders. Both present evidence of chronically repressed rage.¹¹ Attacks of migraine occur when situations are met which intensify the rage without providing opportunity for adequate expression.

Most patients with hypertension see a connection between headache and bowel function. When they suffer from constipation they are ill, and when the bowel moves freely they are speedily relieved of symptoms. This, of course is true for many patients who do not have hypertension, but in hypertensive individuals the relationship is especially obvious. Moreover, it is a relationship which is easily exploited and in which the physician becomes a pathogenic agent when he focuses attention on the bowel as in the days, fortunately not now so common, when colonic irrigations were frequently prescribed for 'auto-intoxication'. It is very difficult to overcome a patient's prejudices—and even those of the medical profession—in this regard. But it does seem to be largely a psychologic association, because relief comes too quickly after a bowel movement to be ascribed to physical causes and in addition, deeper psychologic study often shows the relationship between ideas of obstruction, 'poisoning' and pain in the head.

Patients frequently refer to the symptom of vertigo, which occurs in a great many instances with the head discomfort just described as dizziness or giddiness. Differentiating syncope, which does not imply a disturbance of equilibrium, and true Meniere's syndrome one often finds that the symptom of vertigo bears a definite relation to the anxiety state. Frequently in association with ringing in the ears and sometimes with numbness and tingling of the extremities, it is the result of psychic stress.

The early symptoms of anxiety are usually expressed through the cardiovascular, respiratory, gastrointestinal and genitourinary systems. It is after the anxiety state has persisted for some time that the symptom of vertigo makes its appearance. When it occurs in association with hypertension the vascular disease often is held to be responsible. However, it is well to bear in mind that, like organ language elsewhere,¹² vertigo frequently is the symbolic representation of insecurity, and this is just as true when it occurs in association with hypertension.

¹² Weiss, Edward. The Treatment of Illness of Emotional Origin by the Internist. *Ann. Int. Med.* 14: 424 (Sept.) 1940.

Pain in the precordium, palpitation, dyspnea and fatigue are a group of symptoms frequently associated with cardiac neurosis. Fatigue may be a prominent part of the clinical picture, in fact, the most prominent symptom although again and again the patient speaks of pain in the heart region and only after considerable discussion is it brought out that really the most important symptom is fatigue, that it occurred first, and that only later was pain added. One of the commonest causes of fatigue is emotional conflict, which steals energy which then is not available for useful purposes.

When these symptoms are present with a normal cardiovascular system and general medical examination otherwise is negative, it is not as a rule difficult to assign them to their proper sphere—the emotions. When hypertension is present, however, it is almost invariably held to be the responsible factor. It is under such circumstances that psychosomatic study will frequently reveal that symptoms are out of proportion to disease, that there is much conflict in the personality makeup and that it depends on repressed hostility. Moreover, a specific as well as a temporal relationship will be found between the onset of the symptoms and a psychic event.

SUMMARY OF CLINICAL PICTURE

Headache and various forms of head discomforts, dizziness and constipation, as well as precordial pain, breathlessness on the slightest respiration variety, and fatigue often cannot be explained directly on the basis of the hypertension. They are out of proportion to the disease. When such patients are studied from a psychosomatic point of view it is often found that there is a great deal of conflict in their makeup and an inability to express their aggression directly, and thus it would seem that tensions which cannot be adequately expressed in words or action seek their way out in the circulatory system by means of body language. It is hardly necessary to say that psychologic factors are not the only ones of importance in the clinical picture of hypertension, but they are important because their modification often results in benefit to the patient, regardless of whether the blood pressure figures are lowered or not.

EMOTIONAL FACTORS IN TREATMENT

Psychologic studies show the necessity for a more adequate approach to the study of hypertension than "Are you worried about anything?" and a more adequate treatment than "Go home and take it easy." This kind of superficial psychotherapy, if it may be termed that, is in line with the kind of medical management that has been given to the unfortunate sufferer from essential hypertension in the past.

What has been done in an effort "to bring the blood pressure down"? Because of an ill founded idea that protein was responsible for hypertension and kidney disease, the patient was denied meat and eggs, especially red meat which for some reason was looked on with particular dread. His diet was then rendered even more unpalatable by the withdrawal of salt. Sympathy would doubtless have been extended to this half starved person, except that he probably was not able to eat anyway, his teeth having been extracted on the theory that focal infection had something to do with his hypertension. Perhaps before this he had sacrificed his tonsils for the same reason. In case some food had been consumed, the slight colonic residue was promptly washed away by numerous colonic irriga-

tions, especially during the period when the theory of autointoxication was enjoying a wave of popularity. To add to his unhappiness he was often told to stop work and exercise and, of course, was denied alcohol and tobacco as well as coffee and tea. Then came the use of potent drugs (thiocyanate) and unwise tampering with vital tissues—the partial removal of normal adrenal glands and the application of roentgen rays to the pituitary area—and now the unfortunate person with hypertension has been referred to the neurosurgeon, who is removing more and more of his sympathetic nervous system.

These methods of treatment grew out of our traditional "organic" understanding of hypertension and our emphasis on the necessity for "bringing the blood pressure down" to the exclusion of a more comprehensive and more fundamental understanding of the hypertensive individual. It is freely admitted that the height of the blood pressure is one of the best indexes to the condition and prognosis of the patient with essential hypertension, but to put all of our emphasis on the matter of bringing the blood pressure down is to do the patient an injustice. This is true whether we speak of drug treatment (thiocyanate) or surgery of the sympathetic nervous system. Thiocyanate has brought about blood pressure reduction in many patients but, according to Corcoran and Page,¹³ neither the decreased arterial pressure following sympathectomy nor the therapeutic use of thiocyanate is associated with the undoing of the efferent arteriolar constriction, so that neither sympathectomy nor thiocyanate reverses the process that leads to increased arterial pressure and renal vasoconstriction.

Sympathectomy was first recommended from the standpoint of relaxing a large area of the vascular bed, and only later were the results explained as being due to an increased blood flow to the kidneys. But either measurement of the renal blood flow, even after the extensive Smithwick denervation, showed no significant change or an actual decrease in renal blood flow occurred. To quote Page,¹⁴ "a better explanation appears to be that the decrease of arterial pressure, which follows sympathectomy in man is an expression of denervation of the reactive visceral splanchnic innervation, with resultant partial failure of venous return most evident in the erect posture. The decrease of venous return limits cardiac output and thus tends to decrease arterial pressure. We must also conclude that the operation does not interfere with the fundamental disturbance of the heart and peripheral vessels but that it merely introduces a new, almost accidentally corrective deviation from normal physiology." Again and again we read in papers dealing with the surgical treatment of hypertension that "since the medical treatment of hypertension has failed surgery is justified." I question the failure of medical treatment, our attitude here will depend on our objectives. These must be redefined.

A consideration of this material indicates that essential hypertension is a deep seated constitutional disorder, woven into the very structure and personality of the individual, that it represents a composite of multiple factors, that there is no specific treatment and that at present we cannot speak of cure. Various treatments may relieve symptoms and lower blood pressure, but

¹³ Corcoran A C and Page I H. Renal Aspects of Experimental and Clinical Hypertension. *J Lab & Clin Med* 26: 1713 (Aug.) 1941.
¹⁴ Page I H. Arterial Hypertension. *J Urol* 46: 807 (Nov) 1941.

it is doubtful that we can take away the inherent hypertensive tendency. It is possible that renal extracts, now seemingly in the position of ovarian extracts of a dozen years ago, act physiologically and may come to occupy a position similar to the estrogenic substances that are used so efficaciously as substitutive preparations today. Even then, however, and using the analogy of the menopausal syndrome, we shall still have to think of the personality of the individual with the disorder. We shall still have to try to understand not so much the high blood pressure as the person who has the high blood pressure.

The psychosomatic concept of pathogenesis and clinical picture must impress us with the necessity for the total evaluation of the patient with hypertension. This requires more than lip service to the concept of the organism as a whole. It represents a combined physical and psychological study. Such a study demonstrates that the psyche is one of the many important factors that enter into the etiology and pathogenesis of hypertension and that many of the symptoms occurring in hypertension are of emotional rather than physical origin. For such reasons incapacity often is out of proportion to the disease and therefore it will be found important in a great many patients to reeducate them along the lines of "carrying on" rather than to urge rest and more rest. Menninger¹⁵ champions this idea on the basis that self-directed aggression may be turned outward by the authority of the physician and that extraversion of the aggression, if not too strenuous, may be of advantage to the patient. This was illustrated in case 1.

The knowledge that "every psychic tendency seeks adequate bodily expression,"¹⁶ gives a practical hint in dealing with hypertensive patients. An explanation to the effect that inner tension which cannot be released through ordinary channels (action or words) may manifest itself in the circulatory system by adding to the problem of hypertension represents a rational approach as far as the patient is concerned and often leads to a discussion of problems which are of considerable interest and importance from the standpoint of illness.

To advise the individual involved in mental conflict not to worry is of little value, especially when, as is so often the case, no concerted effort is made to find out what is disturbing him. Too often the physician is satisfied that there are no problems disturbing the patient after he has inquired "Are you worried about anything?" and has received a negative reply. Most of the time the patient really does not know just how much he is disturbed nor does he relate the factors actually responsible for his discontent. He is much more apt to project his worries into questions about his blood pressure, heart, brain and kidneys. Careful inquiry will bring out that his fears are exaggerated and that the reasons he assigns for them are illogical. There is only one approach that has any merit, that is, to encourage the patient to talk about himself as a person rather than as a medical case. Then we shall see that anxiety bears some relation to hypertension, that it, in turn, is related to the unconscious conflict in the personality of the hypertensive individual and that this conflict can often be treated, resulting in relief

of anxiety. But, no matter how the anxiety is related to the hypertension, it is important to analyze and to try to remedy it because, if this factor is managed, the patient can easily become more effective and healthy even if the blood pressure level remains uninfluenced.

There is no objection to the effort to lower blood pressure as long as this does not constitute the sole approach to the problem of high blood pressure. Although the psychosomatic approach does not offer a complete solution of the hypertensive problem and does not even apply to all patients, it is a practical method of dealing with a set of important factors that may be modified, whereas the constitution of the individual cannot be touched. It is an approach heretofore not sufficiently practiced. We are too much concerned with physical measurements in hypertension—the blood pressure figures, the size of the heart, the electrocardiographic tracing, the amount of retinal sclerosis, the percentage of renal function, the urographic study—all of which are essential in the study of the hypertensive person but give incomplete information from the standpoint of the total evaluation of the patient. They should represent the beginning and not the end of the study. We have been too little concerned with the emotional life, which may hold the key to the satisfactory management of the hypertensive patient.

CENTRAL SUMMARY AND CONCLUSIONS

The organic tradition in medicine has been responsible for a narrow (physical) view of the etiology, pathogenesis and treatment of essential hypertension. The psychosomatic approach does not neglect the physical problems involved but includes a consideration of the role of the emotions. It emphasizes the multiple factors in etiology and pathogenesis and attempts to evaluate the resulting composite clinical picture. Such studies indicate that the emotional component apparently is intimately related to the development of hypertension in some patients, to the production of symptoms in many others, and enters into the question of treatment in nearly all patients with this disorder.

Although all varieties of character and neurotic disturbances occur in hypertensive individuals, a common problem seems to be the presence of emotional tension due to chronic repressed hostility. This inhibited aggression (chronic rage) seems to bear a specific relationship to hypertension and, if it can be turned outward by means of psychotherapy, anxiety is diminished and blood pressure is often lowered. Even if blood pressure is unaffected, the treatment often benefits the patient by making him a healthier and more effective personality. Our objectives in treatment should be readjusted. We must do more than try to bring the blood pressure down. We must go beyond the physical aspects of hypertension to the personality of the hypertensive individual in order to be successful in the management of such patients.

269 South Nineteenth Street

ABSTRACT OF DISCUSSION

DR ROY W. SCOTT, Cleveland. Dr Weiss's paper emphasizes the well known influence that psychic factors may exert on the blood pressure levels, as well as the value of psychotherapy in the management of some patients, but it should be recalled that we have no evidence to show that disease of either the central nervous system or the vegetative nervous system is the cause of hypertension.

OTITIS MEDIA AND MASTOIDITIS
IN CHILDREN

A SURVEY OF 1992 CASES

ADOLPH G. De SANCTIS, MD
AND

VINCENT De P. LARKIN, MD

WITH THE ASSISTANCE OF

W. A. GOUGELMAN, BA
NEW YORK

The treatment of otitis media, with particular reference to the results of chemotherapy, has been the subject of extensive controversy in the past few years. The majority of recent reports¹ have been enthusiastic over the decrease in the duration and complications of acute suppurative otitis media under the influence of sulfonamide therapy. Many investigators believe that the decrease in the incidence of acute mastoiditis is a direct result of the increasing use of the sulfonamides. A contrary opinion has been expressed by many others.

METHOD AND MATERIAL

This survey includes observations on all patients with otitis media and mastoiditis who have been admitted to the babies' wards of the New York Post-Graduate Hospital in the years 1931 to 1941 inclusive. In this period a total of 1,992 admissions with otitis media or mastoiditis were tabulated. In a small number of these patients otitis media developed after admission to the hospital, and others had two or more admissions for repeated attacks of otitis media or mastoiditis. We felt that a complete study of the cases of the last six years, 1936 to 1941, should be done because the greatest changes have occurred in this period. There are 932 admissions (773 patients) making up this group and they were studied with a view of determining the age, sex and seasonal variation from year to year, as well as the pertinent symptoms, physical signs, laboratory data, complications, treatment and end results. The 1,030 admissions in the preceding years 1931 to 1935 have

been studied only from the point of view of diagnosis, treatment and end results in order that a base line might be obtained for variations in severity of these conditions from year to year.

AGE, SEX AND SEASONAL INCIDENCE

Fifty-three per cent of all patients were less than 3 years of age, the ages of the remaining 47 per cent being distributed from 3 to 14 years, the upper limit for admissions to our wards. Chart 1 shows the incidence of age by years. The boys admitted numbered 417 as compared with 357 girls, a ratio of 8/7. In the winter and spring, from December through May, 72 per cent of the cases were admitted and only 28 per cent in the remaining six months. The highest incidence occurred in March and April. Chart 2 shows the incidence of admissions by months.

SYMPTOMS

The symptoms noted are those of otitis media, mastoiditis and the commonly associated and complicating illnesses of the 932 children from 1936 to 1941. The origin of each symptom, whether from otitis media, mastoiditis or one of the commonly associated illnesses, is not particularly important because all are related to the same extent that the various illnesses are related. Naturally these symptoms can be considered part of a syndrome of which otitis media and mastoiditis are the main causes.

As might be expected, fever was the most common complaint, occurring in 67 per cent of all cases. An elevation of temperature was noted to be abnormal if it exceeded 101 F. The majority of these patients, however, had temperatures of 102 or more. The next most common symptom was aural discharge, whether unilateral or bilateral, 35 per cent of the 932 patients had aural discharge at some time in their illness, either from spontaneous rupture of the ear drum or from myringotomy. Of the latter group, 13 per cent had bilateral running ears and in 10 per cent it was confined to the left ear and in 12 per cent to the right ear.

Nasal discharge, or a "cold," as it was more commonly described, was complained of in 28 per cent and usually preceded the more severe symptoms by one to several days. Pain in the ear was noted in 27 per cent of the patients, being bilateral in 7 per cent. The importance of this symptom is not adequately emphasized by these figures because it is a complaint of older children only and cannot be well indicated by children under 3 years of age who comprise more than half of our cases. In the older age group, therefore, the complaint of pain in one or both ears is of considerable diagnostic value.

Cough, which is usually part of the associated infection of the upper respiratory tract, was noted in 25 per cent of our patients. Previous ear trouble, either otitis media or mastoiditis, was found in 21 per cent of our patients and usually directed attention to the ears as the source of present illness. Vomiting, either once or repeatedly, usually early in the illness, was surprisingly frequent, in 18 per cent, while anorexia was of sufficient degree to be complained of in only 14 per cent. Diarrhea occurred in 9 per cent of cases during the course of illness. Sore throat falls into a category similar to that of pain in the ears in that it is a complaint of older children, hence its occurrence in only 6 per cent of our cases is somewhat misleading. Swelling behind

the ears, convulsions, hematuria, abdominal pain and nausea occurred in relatively few, the exact figures being shown in chart 3

PHYSICAL SIGNS

The abnormalities that are found on physical examination in otitis media, mastoiditis and commonly associated illnesses were tabulated for the 932 cases from

Chart 1—Age incidence in a series of 932 cases of otitis media and mastoiditis (1936-1941)

1936 through 1941. Chart 4 shows the relative frequency of these physical signs in terms of percentage of all patients noted to have each physical sign.

Naturally the ear drum is the site of the most frequently found abnormality, a diffusely red drum being seen in 85 per cent of all patients at some time during the course of the illness. The remaining 15 per cent of patients comprise the group with chronic and catarrhal otitis media, in whom a different type of ear drum is seen. Whether a single drum was involved or both drums was not recorded for this particular physical sign.

Aural discharge was found in 57 per cent of cases, this figure being higher as a physical sign than was noted for this as an admission symptom, because a number of patients had a myringotomy after admission to the hospital. Bilateral aural discharge was noted in 28 per cent. This particular physical sign is on the decrease because of diminished need of myringotomy since chemotherapy has been used. Injection of the pharynx and tonsils, when present, was noted in 50 per cent. Bulging of the ear drums, usually beginning in the posterior and superior quadrant, was noted in 46 per cent, 31 per cent of the patients were so acutely

Chart 2—Monthly variation in incidence in a series of 932 cases of otitis media and mastoiditis (1936-1941)

ill that special mention was made on physical examination. Postnasal discharge was of lesser frequency, 10 per cent, as was irritability, 9 per cent.

The percentage incidence of the physical signs of mastoiditis is deceiving because they have been calculated from the total number of patients rather than from the number of cases of mastoiditis, in order that

they might have their proper perspective to the entire series of 932 cases. Tenderness over the mastoid was noted in 9 per cent, swelling in 8 per cent, redness in 3 per cent, fluctuation in 2 per cent, sagging of the external auditory canal wall posteriorly in 5 per cent.

LABORATORY DATA

A number of laboratory studies have been done but only a few are of value in this survey because they were done on a sufficient number of our patients.

A total of 782 blood counts, on a similar number of patients, were tabulated. When a patient was admitted with a diagnosis of otitis media or mastoiditis, the blood count on admission was tabulated. When otitis media or mastoiditis developed following admission for some other condition, the blood count at the height of the ear condition was tabulated.

As can be seen in table 1, in 65 per cent of cases there is a moderate to severe leukocytosis (over 10,000 white blood cells), in the majority of the remainder there is a normal leukocyte count. Similarly, there is an increase in the number of polymorphonuclear neu-

TABLE 1—Complete Blood Counts in a Series of Cases of Otitis Media and Mastoiditis

Under 11 Gm	3	30	33	40	33	20

trophils, being over 60 per cent in 55 per cent of cases which is particularly significant, since the majority of our patients are in a very young age group. Conversely, lymphocytosis (more than 60 per cent lymphocytes) is very uncommon, occurring in 10 per cent. Although an average of 41 per cent of patients had a red blood cell count under 4 million and 37 per cent had a hemoglobin content of less than 11 Gm, there has been a steady decline in the incidence of this moderate anemia in the past few years.

Red blood cell sedimentation rates were done on 65 patients. Of these 13, or 20 per cent, exhibited a fall of less than 20 mm in one hour, which is normal, and the remaining 80 per cent exhibited a fall of more than 20 mm in one hour, 51 per cent exhibited a fall of red blood cells of more than 60 mm in one hour.

Cultures for predominating organisms of aural discharges were done in 216 of our 932 cases. Although a variety of organisms could be isolated from cultures of material taken from the ear, the study was limited to three organisms—*Streptococcus hemolyticus*, *Staphylococcus aureus* and the pneumococcus or a combination of these. The same organisms were tabulated for cultures taken from the mastoid.

Table 2 shows the relative frequency with which pathogenic bacteria were found either in pure culture

or in combination. Whenever one organism was found in one ear and another organism in the opposite ear, or two or more organisms were cultured from the same ear, the case was tabulated as presenting a combination of organisms. When only one organism was found in both ears in bilateral and discharge, it was tabulated for that organism alone.

In 73 per cent of cultures from the ear only one pathogenic organism was present, fairly well distributed among the three. 29 per cent yielded *Streptococcus hemolyticus*, 25 per cent yielded *Staphylococcus aureus* and 19 per cent yielded the pneumococcus alone, usually not typed. When two pathogenic organisms were noted, the most common combination was *Streptococcus hemolyticus* and *Staphylococcus aureus*, found in a total of 15 per cent of all cultures from the ear. If the frequency of occurrence of each organism is considered, whether alone or in combination, there is the following shift in the figures. *Staphylococcus aureus* is most common, occurring in 54 per cent of all cultures from the ear. *Streptococcus hemolyticus* is next most common, in 48 per cent, while the pneumococcus is least common, in 31 per cent.

TABLE 2—Pathogenic Bacteria in Cases of Otitis Media and Mastoiditis

The bacteriologic picture in mastoiditis is entirely different from that in otitis media alone. Pure culture of a single pathogenic organism is the rule, the same organism being found in both mastoids when the disease is bilateral. The overwhelming predominance of *Streptococcus hemolyticus* has led some observers to question whether any other organism is of etiologic significance, especially in acute mastoiditis. *Streptococcus hemolyticus* occurred in 80 per cent of cultures taken from mastoids, unilateral or bilateral, without any other organism being present. *Staphylococcus aureus* was present in pure culture in 6 per cent, pneumococcus, usually untyped, in 8 per cent. Two per cent of our cultures yielded different organisms in the opposite mastoids and 4 per cent of the cultures yielded no growth of any organism.

ASSOCIATED DISEASES AND COMPLICATIONS

The commonly associated diseases and the complications which sometimes result from or accompany otitis media and mastoiditis are shown in table 5. Heading the list is the common cold, which was present in 58 per cent of all cases, a total of 539 out of 932 cases. Acute pharyngitis, frequently associated with a common cold, was the next most common condition, in 438 cases or 46 per cent of the series. Pneumonia cannot properly be said to be a complication of ear infections, since

the reverse is more liable to be the true picture. In 16 per cent of our cases pneumonia and ear infections were simultaneously present. Acute hemorrhagic glomerulonephritis occasionally develops during the acute phase of otitis media or mastoiditis and subsides when the ear infection improves. This was noted in 2 per

Chart 3—Symptoms of otitis media and mastoiditis

cent of our cases. Suppurative cervical adenitis, which is usually secondary to an acute infection of the upper respiratory tract, occurred in 41 cases, or 4 per cent of the series. Parenteral diarrhea occurred in 80 cases, or 8.6 per cent. This was confined to children under 2 years of age, and the majority were less than 1 year of age, so that the incidence among this particular group is considerably higher than the figures indicate.

Complications of mastoiditis comprise the remainder of table 5. Subperiosteal abscess or rupture externally through the cortex of the mastoid process occurred in 17 of the 308 cases of mastoiditis in this group, an incidence of 5 per cent. Von Bezold's abscess, or rupture internal to the tip of the mastoid process through the cortical bone, occurred in only 2 cases, or 0.6 per cent. Meningitis secondary to otitis media without mastoiditis occurred in 1 case, with mastoiditis it occurred in 2 cases. Lateral sinus thrombosis and brain abscess were noted in 3 cases each, an incidence of 1 per cent. Encephalitis developed in 2 cases of mastoiditis.

YEARLY INCIDENCE

That there has been a variation in severity and incidence of otitis media and mastoiditis from year to year can reasonably be taken for granted. Such variation

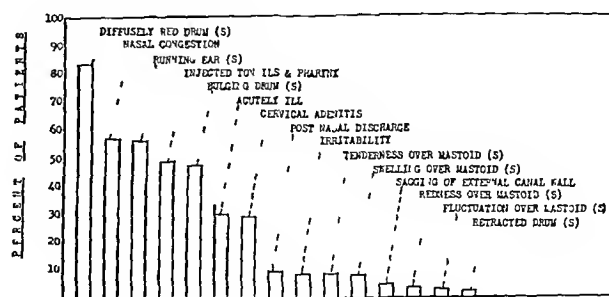

Chart 4—Physical signs of otitis media and mastoiditis

has been noted in most infectious diseases, and there is no reason to suspect that ear and mastoid infections are different. The extent of this variation, however, can be determined only by actual count of the number of such infections over a period of years. The variation in the eleven year period from 1931 to 1941 has been noted in chart 5. There one can see that from year

to year moderate variations occurred, there is a fall in 1940 which is greater than the fall in any previous year. From a total of 274 cases in 1931 and 249 cases in 1937 there is a decrease to 65 cases in 1941, a decrease to one fifth of the peak year—this in spite of a decided increase in number of cases of scarlet fever in 1941.

Chart 5—Incidence of otitis media and mastoiditis (1931-1941)

A further breakdown of these figures, omitting catarrhal otitis media and chronic and recurrent mastoiditis, because they vary as do the more common forms, reveals that there has been a simultaneous decrease in hospital cases of acute purulent otitis media and in acute mastoiditis. A close inspection of chart 6 reveals that from 1931 to 1938 the ratio of acute purulent otitis media to acute mastoiditis approximates closely 2 or 3 to 1. For instance, there were 244 cases of acute purulent otitis media in 1931 to 121 of acute mastoiditis, 148 to 83 in 1932, 200 to 102 in 1933, 178 to 74 in 1934, 134 to 51 in 1935, 171 to 73 in 1936, 175 to 191 in 1937 and 97 to 37 in 1938. There is a sharp increase in this ratio from 1939 to 1941 for, though the number of cases of otitis media decreases, there is a much greater proportionate decrease in acute mastoiditis. There were 79 cases

Chart 6—Comparison of incidence of acute purulent otitis media and acute mastoiditis (1931-1941)

of acute purulent otitis media to 19 cases of acute mastoiditis, a ratio of 4 to 1, in 1939, 46 to 11, a ratio of 4 to 1, in 1940 and 48 to 3, a ratio of 15 to 1, in 1941.

Theoretically there are three important factors that could account for these amazing changes in otitis media and mastoiditis in the past three years. The first is

a decided decrease in the severity of otitis media and mastoiditis, the second possible cause is a radically improved form of therapy, the third possibility is a combination of decreased severity of the diseases in the presence of a more effective form of therapy.

In order to investigate whether there has or has not been a change in the severity of acute purulent otitis media and acute mastoiditis, we have compared the symptoms, physical signs and laboratory data of the 932 cases from 1936 to 1941 in a year by year survey. The symptoms and the relative frequency of each symptom of otitis media and mastoiditis were demonstrated previously (chart 3). A year by year breakdown of these symptoms is presented in table 3. The remarkable consistency with which these symptoms are found from year to year in the same order of frequency and in almost the same percentage of cases in each year indicates that there has been little change in symptomatology of otitis media and mastoiditis. There is usually, in each year, some one symptom which occurred much more frequently than in any other year, such as pain in the ears (1937), vomiting (1938) and nasal discharge (1940), but these are very exceptional. A comparison between the frequency in 1937, a peak year,

TABLE 3—Symptoms in Cases of Otitis Media and Mastoiditis

Aural eia	1	1	0.5	0	7	0

and 1941, the lowest year, reveals practically identical figures for each symptom. Certainly on this basis one cannot claim that there has been a decreasing virulence of the diseases in the last few years.

The physical signs of otitis media and the relative frequency of each physical sign are demonstrated in chart 4. A year by year breakdown of these physical signs is presented in table 4. There is the same relative frequency of each physical sign, with few exceptions, from year to year as is found in chart 4. The one physical sign that shows a persistent variation in the last few years is aural discharge. This has decreased because myringotomy is now much less frequently done than it was five or six years ago. Comparison again of the peak year of 1937 to the low year of 1941 reveals very little variation in frequency of each physical sign. On this basis too one cannot claim that there has been a decreasing virulence in otitis media and mastoiditis in the last few years.

Laboratory data have been broken down in two ways. Complete blood counts were studied in a year by year survey (table 1), while pathogenic bacteria in cultures taken from the ear and mastoid were studied from the point of view of the incidence of the particular organism in the group of patients treated without the sulfonamides and the group of patients treated with the sulfonamides (1937-1941).

A breakdown of the blood counts year by year reveals that a leukocytosis (more than 10,000 white blood cells) was most pronounced in 1937 and 1941 but that the variation in other years was not very great. Similarly, polymorphonucleosis was greatest in 1937 and 1941, but in the other years it did not vary greatly.

A comparison of the frequency with which the various pathogenic bacteria occurred in otitis media and mastoiditis in the group treated with the sulfonamides is opposed to the group treated without the sulfonamides is presented in table 6. The incidence of the three common pathogenic organisms through the period of 1937 to 1941 is almost identical in each group for both otitis media and mastoiditis. These figures differ slightly from those presented in table 2 because the latter includes cultures taken in 1936, which was excluded in the present breakdown because only 1 patient received sulfonamide therapy in that year. Unless it is assumed that the organisms in the cases under treatment with the sulfonamides were less virulent than similar organisms in the cases in which the sulfonamides were not given, it seems clear that this factor is ruled out. There is no reason to make such an assumption.

TABLE 4—Physical Signs in Cases of Otitis Media and Mastoiditis

Retracted drum (s)	2	0	0	1	2	0
Mastoid swelling	7	11	11	7	7	3

On the basis of the fact that over a period of the last six years there has been no significant change in the symptomatology, physical signs and laboratory data, the inescapable conclusion follows that there has been no decrease in the severity of otitis media and mastoiditis in this period. This rules out the first and third possible premises, namely, a decrease in severity of the disease and, second, a decrease in the severity of the disease plus improved therapy for the decrease in incidence of otitis media and mastoiditis.

It seems apparent, then, that an improved form of therapy alone is responsible for the recent changes in otitis media and mastoiditis. A survey of the treatment of otitis media and mastoiditis, therefore, was the next problem under consideration in order to determine what significant changes in therapy have occurred in the past eleven years. The results are recorded in table 7.

Ear drops, as a form of therapy, have not been very popular at any time in hospital practice. Nose drops, particularly 1 per cent ephedrine sulfate in isotonic solution of sodium chloride, mild proteïn silver solution and more recently 0.25 per cent neosynephrin, have been increasingly popular.

Early myringotomy has been considered by some otologists as one of the most valuable forms of therapy

in otitis media. Some excellent studies of large numbers of patients tend to indicate that the incidence of mastoiditis is less in patients with otitis media who receive myringotomy. Despite these facts, table 7 shows that there has been a progressive decrease in the frequency of myringotomy, from a peak of 60 per cent in

TABLE 5—Associated Diseases and Complications in Cases of Otitis Media and Mastoiditis

	Number of Cases in					
	1936	1937	1938	1939	1940	1941 Total

Brain abscess	1	2	0	0	0	0 3
Lacophallitis	0	1	0	0	1	0 2

1935 to a low point of 10 per cent in 1941. This decrease cannot be attributed to a change in the severity of the disease, because it has already been demonstrated that by all possible criteria otitis media and mastoiditis are no less severe than they were in the past. None the less, with myringotomy done far less frequently, mastoiditis continues to decrease.

Irrigations of the ear three or four times daily with saline or boric acid solution have frequently been used in the treatment of purulent otitis media. However, in recent years this method of therapy has been gradually abandoned. In 1937 it decreased sharply and has not been in common use since that time. Tonsillectomy and adenoidectomy and sinusotomy in the treatment of otitis media and mastoiditis have been confined almost entirely to the cases of chronic involvement and are not of significance in our study.

The incidence of mastoidectomy reflects fairly accurately the incidence of mastoiditis itself and decreases in proportion to the total number of cases in any one year. Mastoidectomy is even more frequent than mas-

toiditis in a few years (1932, 1933) because of mistaken diagnosis in some cases and also because it was the vogue at that time to resort to this surgical procedure if a so-called parenteral diarrhea did not respond to medical treatment—this very often in the absence of signs of actual mastoid disease.

The use of the sulfonamides in the treatment of otitis media and more recently of early mastoiditis in addition

has gradually gained prominence in the past six years. In 1936 only 1 patient received such therapy, an incidence of 0.4 per cent. In 1937, 13 per cent received sulfonamide therapy but many of these only after mastoidectomy had been performed. The latter group has been discarded from our statistics on sulfonamide treated patients. After 1938 the percentage of sulfonamide treated patients rose rapidly, reaching 77 per cent in 1941. This is shown in chart 7. In 1942, although not included in this study, practically 100 per cent of the patients have received the sulfonamides.

In 1937, 1938 and 1939 sulfanilamide was the most commonly used sulfonamide derivative, with only an occasional patient receiving azosulfamide or sulfapyridine. In 1940 sulfathiazole was used in increasing amounts and in 1941 sulfadiazine was used to a small extent, the latter two drugs replacing sulfanilamide entirely in the treatment of otitis media. Treatment was considered inadequate if a patient did not receive approximately 1 gram (0.065 Gm.) of a sulfonamide per pound (454 Gm.) of body weight in a twenty-four hour period and if the drug was not continued for a minimum of three days. The few cases that fell in the

the sulfonamides in every single year. It is of interest to note, however, that a total of 151 cases were studied in 1939 and that the results in the two groups are almost identical. This number of cases over an entire year might ordinarily seem to be an adequate study, but in the light of the remaining years it is obvious how misleading such a survey would be in as large a subject as otitis media and mastoiditis.

TABLE 7—Treatment of Otitis Media and Mastoiditis

	Percentage in											
	1931	1932	1933	1934	1935	1936	1937	1938	1939	1940	1941	
Ear drops	1	1	1	0	1	2	0.5	1	22	5	1	
No e drops	11	13	15	11	11	33	41	47	40	67	31

Sinusotomy						0	0.4	0	1	0	0	
Sulfonamides	0	0	0	0	0	0	13	90	33	34	77	

From these figures, it is clear that the sulfonamides have played the dominant role in the amazing changes that are occurring in otitis media and mastoiditis.

Our present routine for otitis media is to give the patient sulfathiazole shortly after admission to the hospital, the dosage being 1 gram per pound of body weight in a twenty-four hour period, divided into six equal doses. A complete blood count and urinalysis are done before the drug is started. Urinalysis is done daily and a blood count every other day during therapy. Nose drops, either 1 per cent ephedrine in saline solution or 0.25 per cent neosynephrin solution, are given to relieve the associated nasal congestion. Pain in the ear, when present, subsides within six to ten hours even though no change is seen in the ear drum. Full dosage is continued for four days after the temperature has returned to normal or two days after aural discharge, when present, ceases. Then two thirds of the original dose is given until the ear drum has approximated a normal appearance. The sulfonamides are given for a minimum of seven days and usually not longer than fourteen days.

TABLE 8—Acute Mastoiditis in Cases Treated With and Without Sulfonamides

Chart 7—Treatment of otitis media and mastoiditis with the sulfonamides

group of the inadequately treated have been arbitrarily discarded from our statistics. Although we have not had a complete breakdown of our statistics of 1941 and 1942, it is our impression that sulfathiazole is definitely the drug of choice, with sulfanilamide and sulfadiazine about equal but secondary choices in the treatment of otitis media and early mastoiditis. In 1942 (not included in this study) approximately 60 patients have been treated with the sulfonamides, sulfathiazole and sulfadiazine being used in an equal number of cases. It may be of significance to note that no child who received sulfathiazole developed mastoiditis, whereas 2 of the patients who received sulfadiazine developed surgical mastoiditis.

Comparison of patients adequately treated with the sulfonamides with those treated without sulfonamides from 1937 to 1941 is presented in table 8. A total of 162 patients received adequate sulfonamide therapy of whom 15, or 9 per cent, developed acute mastoiditis and required mastoidectomy. A total of 506 patients with similar conditions in the same period were treated in the usual way but without the sulfonamides, and 156, or 30 per cent, developed acute mastoiditis and required mastoidectomy. A breakdown of these figures reveals that mastoiditis was less frequent in the sulfonamide treated group than in the group treated without

When the patient enters the hospital with pain or tenderness over the mastoid, the same procedure is followed but an emergency roentgenogram of the mastoid is taken if the patient is over 1 year of age, in an attempt to discover whether degenerative changes have occurred in the bone. If there is no degeneration, the condition usually subsides without surgery but must be watched carefully and another roentgenogram taken to determine whether mastoiditis has been masked. If degenerative changes are already present in the mastoid sulfathiazole should be given but mastoidectomy will probably be necessary.

SUMMARY AND CONCLUSIONS

1 Over in eleven year period 1,992 children with otitis media and mastoiditis were admitted to the babies' wards of the New York Post-Graduate Hospital

2 The 932 cases in the last six years 1936 to 1941, were studied in great detail as to age, sex and seasonal variations, the symptoms and physical signs of otitis media and mastoiditis and the relative frequency of each

3 A year by year breakdown of symptoms, physical signs and laboratory data reveals that there has been no decrease in the severity of otitis media and mastoiditis in the last few years

4 There has been a decrease in the reliance of incisions of the ear and myringotomy in the treatment of otitis media

5 A comparison of the group of patients treated with sulfonamides against the group treated without sulfonamide from 1937 to 1941 shows an incidence of mastoiditis of 9 per cent in the former and 30 per cent in the latter

6 Sulfathiazole is the drug of choice One gram per pound a day is the recommended dosage

5 East Eighty Fourth Street

ABSTRACT OF DISCUSSION

DR VINCENT DE P. LARKIN, New York I have one word to add, which Dr De Sanctis did not have time to speak about, namely the final breakdown of our cases into a group of control and sulfonamide treated from 1937 through 1941 Patients with acute otitis media who did not receive sulfonamides had an overall incidence of mastoiditis of 30 per cent Through that same five year period, similar cases treated with sulfonamides had an overall incidence of mastoiditis of 9 per cent, and actually in the last year our incidence of mastoiditis fell to 3 per cent in the sulfonamide treated group We feel that this control series as opposed to the sulfonamide treated series proves fairly conclusively that the one responsible agent which has produced these remarkable changes in the incidence of mastoiditis is chemotherapy

DR ADOLPH G. DE SANCTIS, New York Sulfathiazole is our drug of choice, and we use about 1 gram per pound daily divided into six doses I think it is important to stress that the sulfonamide drugs should be continued for at least four days after all symptoms and signs have disappeared They were not included in this study, but the cases admitted in 1942 to our wards represent about 60 children About 30 of those received sulfathiazole and about 30 received sulfadiazine No child who received sulfathiazole developed mastoid disease Two who received sulfadiazine did That may be a coincidence but it strengthens our impression that sulfathiazole is the drug of choice

Cardiac Murmurs—The stethoscope did not dispel the notion that all heart lesions were serious To a certain extent it augmented it The murmur revealed by auscultation became a bugbear, it was misinterpreted as meaning a damaged valve and as ominously threatening an early death This was the impression made upon me by the teaching in the medical school in 1888 Though functional, hemic, accidental and meaningless murmurs were written about, only too often the physician spread gloom as he warned the parents of the presence of the murmur that threatened disaster No wonder that Mackenzie later indignantly inveighed against the prevailing interpretation of the systolic murmur and declared the stethoscope to be not an instrument of precision but of error The fault, however was really in the brain of the listener and not in the instrument—Herrick, James B A Short History of Cardiology, Springfield, Ill., Charles C Thomas, 1942

THE WARTIME CONTROL OF VENEREAL DISEASE

PROBLEMS IN THE APPLICATION OF RECENT SCIENTIFIC DISCOVERIES

JOHN H. STOKES, M.D.

PHILADELPHIA

The venereal disease control field is a perpetual Christmas pudding and full of surprises As Little Jack Horner (whom I may be supposed to impersonate for this occasion) puts in his thumb and pulls out a plum, with his well known expression of egotistic self satisfaction, little does he realize that his find will presently be shown to be a raisin or even a California prune, and a dried one at that In fact, to extract even prunes from the assigned pie, Jack has had to ask permission, first, to talk about problems rather than solutions and, second, to include some new and surprising developments from old discoveries I propose to discuss four groups of problems those of the recently discovered fallibilities of the case uncovering or diagnostic methods, the problems of foreshortened treatment, the problems of prophylaxis and the influence of ultraeffective treatment on morale and the future of venereal disease and the sex life

THE FALLIBILITIES OF THE UNCOVERING MECHANISM

The serologic tests for syphilis have recently been subjected to heroic reevaluation Formerly used for the examination of the sick, and to a large extent for those in whom some suspicion of the need for it actuated the doing of the test, the negative result was first shown to have a margin of unreliability that made it unable to stand alone or without repeated confirmation by laboratory and clinical examination The positive received a rising vote of confidence The past five years, the era of the Wassermann barbecue and the wholesale application of serologic tests to large groups of the well, have now shown the positive test, no matter by what methods or how rigorously performed, to have a margin of nonspecificity of disturbing proportions The presence of syphilitic reagin in normal persons, its rise and fall under drugs, diseases and unexplored factors, the uncertainty as to its whereabouts, mode of generation and actual nature, its absence in undoubted syphilis with characteristic manifestations, the anxious attempts to define by such methods as verification tests, so called, by quantitative procedure, by spirochetal antigens, including even the Reiter strain, whose superior specificity approaches the ludicrous when men of the experience and caliber of Kolmer suspect it of being *Treponema macrodentum*, a mouth spirochete, and not *Treponema pallidum* at all, all these considerations and many more have given the thoughtful observer a real case of sero-jitters Imagine the plight of the practitioner the examiner passing on selectees, and the syphilologist, as the list of diseases known to be responsible for the appearance of reagin-like substances in the blood grows and grows, and the time after their occurrence in which false tests remain positive stretches from days to years No longer is it possible to take refuge behind the belief that mere oversensitiveness of test procedure is responsible for the decline in reliability

Read at the Conference on Venereal Disease Needs in Wartime United States Public Health Service Hot Springs, Ark. Oct. 21, 1942
From the Institute for the Control of Syphilis and the Department of Dermatology and Syphilology University of Pennsylvania School of Medicine

of the positive report. It is true that the wholesale use of screen tests, even the best recognized of which have their slippery edges, has led to confusion, not wholly corrected by the performance on positive serums, of one of the basically more stable procedures. But the trouble lies deeper than that—as deep as our ignorance of the nature and identity of the syphilitic reagin and its congeners, and that ignorance is profound indeed. The serious search for the substance suspected of being a serum protein or globulin fraction is now on under the auspices of National Research Council supported investigations, armed with chemical fractionation of plasma or serum and with Tiselin—a word to conjure with. One might suggest that the “reagin” may turn out to be anything but a substance—rather a relationship or variable balance or proportion between substances or fractions, or a mode of reaction at varying concentrations and electrolytic conditions. But whatever it is, it must now be found if we are to filter out the dross from our years of confidence in serologic tests for syphilis.

Is it really as bad as that? Well, hardly ever. I still presume to believe that there is some common sense that will produce at least a common denominator for the situation. Let us attempt one.

The blood test for syphilis has always been recognized as unfit to stand alone, it is a reproach to use it as a sole basis for treatment, it cannot decide either way the question of infectiousness even. There then goes much of its public health significance. In the absence of clinical signs of syphilis it has at the most discovered only latency. That and congenital infection is, at least as I have been observing it, overwhelmingly the harvest of its wholesale use to determine physical status and fitness anywhere. It is strongly, repeatedly and incontrovertibly positive by any reliable or so-called standard method of performance, early in the disease though not quite at the start. The seesaw of weak positives and conflicting laboratory and varying method reports has been shown subject to confirmation, to be largely technical stuff. It is strongly positive, or there are strong positives in a series, in asymptomatic neurosyphilis as a rule. The relatively rare exceptions are like late tabes, brain gumma, and so on, accompanied by diagnostic signs. Liver, spleen, bone, eye, gastrointestinal tract lesions and congenital infections are apt to be inescapably positive. If they are not, something is seriously wrong with the laboratory. The syphilis most likely to escape a serologic uncovering mechanism backed by reasonably competent examination is that of the pregnant woman especially the multipara, and the early cases of syphilitic vascular and cardiovascular disease. The fluoroscopic examination of the heart and great vessels and the spinal fluid examination can prevent casual misinterpretation of serologic positives or negatives, whether they represent latency or progression, in the large majority of cases. The positive diagnosis of syphilis can, then, be made safe. Its elimination, however, once the suspicion is aroused by a test, has always been difficult and probably will long remain so. Certainly even with our present armament of tests and examinations, x-ray and spinal fluid included, one hesitates to tell a person who has chalked up a strong serologic suspicion or a woman who, facing marriage and pregnancy, has chalked up a weak one, not to take treatment. They had better treat for life insurance. While we are searching for the ultimate reagin key to the situation, then, let us remember that most syphilis is latent. The age of the latency tends to be propor-

tionate to the age of the individual, syphilis being a disease acquired in youth. Early latency should be vigorously, and later latency in middle life should be moderately treated. The issue thus becomes one of implementing a policy, for no person with syphilis, latent or otherwise, should be put in a position where he is denied treatment. Persons with latent syphilis are competent, and treatment does not interfere with an acceptable level of efficient performance. What to do about latent syphilis thus becomes a question of the value to the particular occasion of the particular syphilitic person and of his effective placement. Most of the occupational discriminations, except for domestics, are bosh. Is he worth the treatment he should be given? On the yes or no to that, in the individual case, answered by the Army, the Navy, the public health or other authority, the question of what to do with syphilis in available tests ends.

The serologic tests for syphilis are not the only ones that disturb. There is reason to suspect that there has long been a serious margin of error in darkfield identification of the organism by the inexperienced. Mahoney has said that at mouth and anus *Treponema pallidum* and *Treponema macrodentium* are indistinguishable. After seeing some of what purports to be *Treponema pallidum* in current moving pictures, one begins to wonder whether the only real one is that observed by darkfield from lymph nodes and from scraped papules on the glabrous skin in undoubted secondary and recurrent eruptions, to whose diagnostic value we have repeatedly called attention. Nonsyphilitic endourethral and gastrointestinal spirochetes have appeared on the investigative horizon to disturb such fundamental hypothetical conceptions as the infectivity of semen and the identity of syphilitic gastric ulcer. It is therefore a question whether the tremendous cost of equipping every clinic, however inexperienced its staff, with darkfield apparatus is worth while, whether even urologic clinics should have darkfield equipment at all, even whether daily serologic tests by a sensitive technique do not identify the disease soon enough. Such indeed is reputed to be the practice at a number of points. Granted quarantine control of the infectiousness of the individual during the seronegative phase of a developing infection, the feeling is understandable that one would rather postpone treatment until one is sure, than begin on untrustworthy darkfield evidence. But is one surer with a single positive blood test? The greater treatability and curability of the disease before serologic tests become positive is now so far established both for old and foreshortened new methods that an adequate darkfield diagnostic setup is still to be desired. One might rather treat for syphilis a patient with a lesion in which the organisms found by a not too inexperienced examiner are probably *Treponema pallidum* than to take all the chances involved in waiting for a delayed serologic diagnosis. When in addition to experienced judgment lymph node and lesion aspiration and other refinements are possible, the trustworthiness of the darkfield procedure increases greatly. Thus, then, is an argument for the laboratory or clinical diagnostic center, where expertise can be concentrated rather than for the dispersed station or small clinic distribution of darkfield facilities.

The diagnosis of gonorrhea is not in my field, but the presence of some serious perplexities there is apparent to any one. Smear diagnosis with an accuracy of 7 to 30 per cent, especially in women, and cultural diagnosis 12 to 60 per cent, leaves much to be desired.

The *Micrococcus citrihilis* revisions in our conceptions of vulvovaginitis in children are good illustrations of how far we have gone wrong in microscopic identification of gonorrhea in the past.

I am unable again to argue the minutiae of such points, but when an authority can say that it is impossible to determine whether a woman is or is not a carrier of gonococci, it is clear that the reservoir problem for this disease is unsolved, and the immediate question seems rather one of how safe it is to treat every woman who is running a risk rather than every one who demonstrably has the disease. Again, as in syphilis, suspicion and presumption are tending to outstrip diagnosis and certainty. It becomes the easier to adopt this point of view, in both fields, as treatment becomes simpler and safer and shorter, and the pressure for and urgency of control in an emergency situation becomes more intense.

FORESHORTENED INTENSIFIED TREATMENT

Foreshortened treatment for syphilis is no novelty. For years the patient and the doctor have been practicing it in the form of the few weeks or months of arsenical and heavy metal treatment so generally employed in the average case over two of the decades since 1911. It has in recent years become apparent, and the principles should be borne in mind in interpreting all foreshortening and intensification plans, that

1 Syphilis cures itself or at least comes to seropositive arrest with little damage, in an unknown percentage of cases, probably ranging around 40 to 50 per cent.

2 A relatively small amount of treatment, if it does not of itself bring on relapse in one form or another, through disturbance of the defense and immunity reactions, is capable of raising the expectancy of cure to an unknown but considerable degree. In seronegative primary syphilis this may well be guessed to be as high as 70 per cent, to judge by the good results so widely reported for the now out of date "abortive cure" systems.

3 Any system, no system, and even no treatment at all in syphilis has a running start toward cure, then. The intensification and the prolongation of treatment that expresses itself in 1,200 milligrams in five days or thirty arsenical and sixty bismuth injections in eighteen months is directed at a relatively small segment of unpredictably resistant infections. These resistant infections will either (a) maintain the reservoir of infective disease by relapse, (b) be responsible for infected children or (c) lead to serious consequences, especially in the cardiovascular and nervous systems of adults.

4 Any new systems proposed should be judged basically by their ability (a) to equal or surpass the "curative" expectancy of the old ones, (b) to lead to less infectious relapse, (c) to cure more mothers and protect more children, (d) to reduce the incidence of cardiovascular and neurosyphilis and (e) by their relative risks to the patient.

5 For the evaluation of a system, time and observation are necessary to establish reduction of or absence of relapse and progression. For the former, two to four years, for the latter, up to ten years is a reasonable observational requirement. For decision on relapse the patient must be repeatedly and frequently observed, for it is a come and go affair. For the evaluation of "cure" from a decade to a lifetime the longer the better is required.

6 A system which under such scrutiny has shown itself at least equal to its predecessors may then proceed to claim additional advantage and support for a variety of reasons, including cheapness, rapidity, controllability of the lapse factor because the whole job is finished in a short time, and in the widening of availability of treatment by making possible the treatment of more persons per unit of time, personnel and equipment. Such considerations are in the main secondary to those of control of infectiousness and real curative power.

7 If the new system equals the old or surpasses it in all these particulars it has but one more hurdle to make before achieving priority. While *primum non nocere* is losing some of its meaning in a war torn world, there are still arch conservatives who are inclined to examine critically the bad effects, the complications of a system. Of real importance to the victim are the risks involved, the chances of damage or of death from treatment in the case of a disease which with none or very little treatment gives the victim at the outset a 40 to 70 per cent chance of escape from serious consequences. If an equal chance of escape with an older method offering less risk exists, only the most cogent reasons and a free choice by the patient justify the selection of the more dangerous method.

What is an experimental method? A method remains in the experimental zone, syphilotherapeutically speaking, (a) until everything that can be found out on animals has been found out, including the direct effects on both the disease and its carrier, of the method itself, actually applied. While the results of trial on animals may prove disappointing, equivocal and for various reasons inapplicable to man, methods must be tried on animals to see whether the results are interpretable or not. (b) The method must next be applied to man, using the lessons learned from animals. (c) When thus applied the method must now show its morbidity and mortality for man clearly and unmistakably, and (d) its efficiency in man must be judged by the criteria enumerated.

Some experiments must use man as the guinea pig, for animal methods are not applicable, and most methods must have their final experimental test on man. It is unfortunately true that shortcutting from lack either of ingenuity or of facilities, or from a disposition to rush results is common and increasing practice. In times of emergency the delays of animal study may be critical.

The test on man will gain in significance to some extent with increasing numbers, but more with repeated cold evaluations. Cold evaluation, experience shows, is a secondary not a primary characteristic of the clinical mind. From this fact derives the deflation which most enthusiasms for agents and methods gradually undergo. It is therefore not intrinsically improper or evidence of a jealous nature or a sour outlook to oppose the modest exuberances and enthusiasms of discoverers with searching questions as to procedure and the establishment of fundamental facts. To label a method as a result of such questionings "still experimental" is not to damn it or even to discourage its use whenever and wherever patients and their sponsors are, after a frank exposition, disposed to accept it. There is precedent for volunteering and there is at the other extreme such potential abuse of volunteering that malpractice law interpretation even provides that the patient in some situations shall not be held to a decision as to the propriety of a procedure which may risk his life and health. I take the discussion of intensified treatment for syphilis this far into the philosophy of new methods,

because the phrase "still experimental" used in connection with such systems has aroused bitter acrimony and feeling prejudicial to the interpretation of the merits of the procedures. That they have merits no sane person can deny. That they will probably, with improvements suggested by the experimental work on animals that should have been done long ago, and further improvements suggested by the not always inevitable use of man as the experimental animal, be important, even preferred procedures in the future, any experienced mind will concede. That these methods or any one of them can now be tried out on as large a scale as any authority, civil or military, which can offer human beings for a pretty well tested but still experimental venture desires is also self evident. To be specific if the Navy, which established a precedent in the displacement of complement fixation in diagnosis by the Kahn test, should now wish to displace an old and by its own records very safe if long drawn out treatment procedure with a short and less finally evaluated one, it should do so, assuming the responsibilities involved. But if an organization like the Army should say to an advisory group "We do not wish to be placed in the least danger of being accused of using the authority we have over the lives of men to subject them to experimental procedure" then the advisory group has no recourse other than to say that foreshortened intensified treatment, and especially the five day massive dose method, is not as yet fully evaluated, is still an experimental procedure and must in all probability be further modified to do away with serious objections, retaining its undoubted values as far as possible unimpaired.

Let us now try to bring this problem of foreshortened intensified treatment methods down to earth by a summary of pros and cons, which unfortunately I have not been able to reduce to the deadly parallel column because of the multiple modifications involved.

First, let us recall that intensified treatment was proposed for the management of early syphilis, a critical problem, none more so from the individual and public health standpoint, but only 12 to 20 per cent of the whole treatment problem in its proportion to the great mass of latency which is the bulk of the people's syphilis. In emergency situations, in which for defensive purposes large blocks of persons must be provided with maximum treatment for protective or "insurance" purposes, intensified methods might be the most useful but have been the least applied. They would probably too involve the greatest risk.

But since latent syphilis is the least dangerous aspect of the disease from any standpoint, and generally conceded to be much overtreated, the wholesale application of an ultraintensive method to this less serious 70 to 80 per cent of the problem, with greatly increased mortality risks, hardly seems a desirable approach. The only situation which compares closely with that of early syphilis in urgency is that of the pregnant woman. For her, on the other hand, increased mortality risk by intensive treatment may mean two deaths instead of one, and it has quite generally appeared from various studies that comparatively little instead of much treatment, if begun before the fifth month, is adequate for the protection of the child. The pregnancy itself is even likely to reduce the ultimate seriousness of the disease for the mother. It would seem then that there is real doubt whether there can be any justification, except when the infection is discovered late in the pregnancy, for the treatment of pregnant women by

ultraintensive technics. There has been some reason to believe that the capillary system of the brain and the hemopoietic mechanism, both subject to idiosyncratic types of reaction to the arsenicals in man, are more rather than less susceptible in pregnancy and hence provide the fatal treatment reactions.

Now let us ask ourselves just what is gained by concentrating an entire course of drug therapy into a few days as compared with a few months or years? Is there a more rapid extinction of surface spirochetes and quicker rendering of the patient noninfectious by rapid than by slow methods? Apparently not, for the disappearance of spirochetes within twenty-four hours follows the administration of small or normal doses of mapharsen by any technic. Do spirochetes reappear less promptly or less often in recurrent or relapsing lesions after rapid than after slow methods? Apparently not, the proportions of mucocutaneous relapse, 5 to 15 per cent, are apparently much the same in the two. It occurs most frequently in the second to the fourth month after intensive therapy and after the close of treatment (second year) or during inadequate or irregular treatment in slow methods. The prolongation of treatment may defer the relapse tendency but intensification does not greatly reduce it apparently. In fact, here again the disease seems to assert its biologic rights over all variations in the mode of treatment. Those who will relapse will relapse. No time or frequency is saved by either method.

But the leading time argument involved in intensification runs somewhat as follows. We have our hand on the patient today. If we can put into him in five days sixty-five weeks of treatment, think of the time we have saved. (Think too, of course, of the lead we have on the disease, if the patient is a hyscr, disappearing after taking only a fraction of what we planned to give him in the longer time. He is committed willingly. But of that presently.) Examining the time question, the man hours, involved in treatment by rapid and slow methods, we find sixteen and one-half days estimated as the time lost in treating a sailor for a fresh syphilis by the long schedule and fifteen days by the short schedule, the latter including the tests for fitness to receive and the time required to recover to working capacity after the new treatment. This is hardly the time saving of 90 per cent recently claimed by the most vocal advocate of the fast school. It comes nearer being 10 to 50 per cent. Even estimating that a clinic patient loses a half day each time he takes a treatment, the total is thirty-two and one-half days for a long course, not sixty-five weeks as one might picture it. And with properly placed and timed clinic or private facilities, including night clinics, the man-hour cost of the long system can be ironed down still further. There is, then, something deceptively glamorous about this time saving business. What is being advocated is not so much real time saving as the appeal expressed in "Come and have it over with."

It is contended that "CHIOW"—"Come have it over with"—will do away with the burdens and deficiencies of case holding (follow-up), the shortcomings in adherence to treatment alleged to be so general, and will get into the patient disposed to lapse for once and all, what he needs for his cure. On examination of this conception it too is seen to contain some criticizable elements. First, it is implied that observation and case holding cease to be so necessary once the treatment is undergone. They are being performed for scientific purposes, perhaps. As a matter of fact, unless the patient is fol-

lowed as consistently in the one system as the other, recurrence and relapse, pregnancy and its problems, and the slow onset of cardiovascular and perhaps even neurosyphilis not fully excluded by one negative fluid, go on unrecognized and unchecked. The obligation to follow up patients being given a five day course for the two to four years that represent the infectious relapse and recurrence period of the disease is just as mandatory as to keep a patient being given an eighteen month course coming for a similar period. There can be no prediction—even less than with the slower methods, perhaps—is to which patient is “cured,” which will have a relapse, at the time the patient is discharged to observation. With the longer intervals between check examinations and tests in the short systems, evanescent come and go of infective lesions and the temptation to disappear for good have just that much more chance to complicate the problem. No serious study has been made thus far to my knowledge as to which system, the long or the short, tends to hold the patient better to the years of obligatory observation. But even the proving of patients substantially, to return after their five day courses, could not forestall a loss rate of 17 per cent. Losses have ranged from 10 to 20 per cent in other series. This is undoubtedly very low, but it has been secured in some substantial series over only a short period (six months). Proponents of short systems cite by suggesting that 5 per cent of cases adequately treated is all that the properly operated modern clinic equipped with competent contact tracing personnel can accomplish. Long term treatment in such clinics is satisfactorily carried through in 25 per cent of early cases, and 50 per cent receive ultimately satisfactory but irregular treatment. In really good clinics, too few in number it must be admitted, with effective case holding methods, 50 per cent of patients measure up to the full standard, 70 to 80 per cent receive ultimately satisfactory though irregular treatment. This still gives foreshortened intensive methods an unknown but probably good lead over older methods in the number of persons who actually get the maximum of drug pumped into them for the cure of their disease and therefore carry around with them from the day of their discharge the 75 to 100 per cent outlook for cure claimed by both long and short systems.

Another point insisted on by proponents of shortened intensive treatment is the reduced cost of the procedure. Hospitalization for the slow five day drip, with the laboratory tests involved, cost at the start about \$90, and if a subsidy must be paid for follow-up visits the cost would probably be some \$20 higher. It can probably, however, be substantially reduced. A cost of \$100 per patient is from 25 to 35 per cent higher than the cost of a long system cure to the patient in a part pay (not a free) clinic of high rank. Ambulatory multiple injection techniques are of course capable of reducing the cost much further than did the original hospitalization methods.

All in all then, without even getting down to the last critical essentials, foreshortened treatment is a less obvious beneficence than those who wish now to make it universal have claimed it to be.

And now for the hard pan of the matter. What can foreshortened treatment, whether by drip or by multiple injection, and it may be added with pyrexial therapeutic accompaniment, at least in systems requiring fifteen days or less for their completion, claim for itself? First, an accomplishment in terms of “cure” in seronegative and seropositive primary and in secondary syphilis,

equal to but not as yet demonstrably superior to the best of the old methods. Second, in some modifications, reduced time and expense, a widening of available treatment facilities, important in time of emergency and under certain conditions especially affecting the armed forces, the merchant marine and so on. With these gains, which are the only outright gains apparent, they sustain a grave reverse in the form of a mortality from hemorrhagic encephalopathy based on 4,841 treated cases, all methods, of 1 in 220 cases, and a morbidity from encephalitis (nonfatal) of 1 in 160 persons treated. This should be compared with an incidence of encephalopathy by the older methods, estimated at 1 in 20,000 cases, and a total of recorded deaths from mapharsen used in now uncounted hundreds of thousands of cases, not to say millions of injections, of only 6 reported cases. Time does not permit full discussion of the experience of different observers of intensified treatment with figures ranging from 1 to 10 to 1 to 400 mortality. The general indications at this stage of development of intensive procedure are that the death rate will be from one hundred to two hundred times that of older, slower but, when effectively applied, equally effective methods.

Shall this higher mortality, in the absence of significantly higher therapeutic effectiveness, influence the placement of the method in a warring world? It is easily conceivable that there will be situations in which with the expertness and hospital or treatment center facilities available on which, all proponents of short methods insist, time may become so valuable or those destined for death so “expedient” that the methods must and should be employed. The decision to employ them in this fashion does not lie within the recommendatory power of any advisory body, as the National Research Council Venereal Disease Subcommittee has indicated, unless that power feels it can assume responsibility for an as yet unevaluated and not intrinsically uncriticizable experiment.

To leave the problem at this point would be to ignore the direction from which light and hope are coming, and the truly experimental contributions on which it is based. The admirable work of Eagle and Hogan, destined to become a classic of its kind, indicates that there is in the experimental animal a margin of safety which varies with the prolongation of the treatment. A compromise can apparently be found in which what appears to be the total curative dose of the arsenical (estimated at 20 to 30 mg per kilogram in man) can be given within a time that provides an optimum of safety under the conditions. Apparently this time seems to be somewhere between six and ten weeks, the drug being administered in man in equal doses of 40 to 80 mg at the rate of three injections a week. A group of forty cooperating clinics whose total patients treated has now reached 1,100 is employing four, six, eight and ten week “courses” with thus far one death reported from nephritis apparently complicating syphilis rather than treatment, and one nonfatal encephalopathy. The four week cure has been dropped as unsatisfactory. Shafter and others have added bismuth to the short arsenical courses and are strongly impressed with the better treatment results with less arsenic and the lowered incidence of complications.

The direction from which I myself seem to see the most of promise has unfortunately been unwaveringly expanded from a ray to the flare of a super nova!

one of de Kruif's premature imaginative explosions. From a steadily extending experience with combined fever and chemotherapy in the treatment especially of resistant syphilis we are coming to believe that the beneficial influence of fever in stimulating defense extends all through the disease and that an arsenical, as suggested by Simpson and his co-workers, is if anything better tolerated during pyrexial therapy than at other times. From even our small experience with typhoid pyrexia plus trypanamide, arsphenamine, neoarsphenamine and mapharsen, we are convinced we can get effects on highly resistant syphilis, which, as noted is the syphilis against which all our super efforts are really directed, that can be secured in no other way that we have tried. We are prepared to hope, therefore, that the combination of one, two or three sharp and prolonged pyrexial rises with massive dose mapharsen therapy by drip or multiple injection may greatly enhance the possibility of cure and shorten the time required without alarmingly increasing complications. As yet we have no system to offer or endorse. Careful experimental studies as yet unpublished, from other sources, seem to indicate that in experimental animals, while the tolerated dose of mapharsen decreases at fever levels and toxicity increases, the effectiveness of the drug increases far more rapidly.

SOME PROBLEMS INVOLVING GONORRHEA

Neisseriologists apparently will soon be confronting some of the anxieties and doubts of the syphilologists over a massive dose single treatment for gonorrhea. The reports of Miescher and most recently of Pappas indicate that single doses of 2, 3, 5, 6 and 7 Gm. of sulfathiazole cause the disappearance of organisms and symptoms and the apparent cure of uncomplicated cases as effectively and in about the same time as repeated doses. The results with sulfadiazine, still under study, seem especially good. They raise the same question we encounter in massive dose syphilis therapy. Apparently the first 2 or 3 Gm. cures a high proportion. The rest of the cure is unnecessary or directed at the resistant few. Thus in gonorrhea we are approaching rapidly the problems of follow-up after as contrasted with case holding before. Relapse versus reinfection, late toxic effects, serious progression under cover of negative cultures and absence of acute symptoms will perhaps become as familiar as in the syphilis field. A particularly interesting question is raised by the increasing evidence of cumulative toxicity and of sensitizing power on the part of the sulfonamide drugs. Their repeated use leads in about 26 per cent of patients with other medical conditions to fever, rashes and other toxic allergic manifestations, which make increasingly difficult their use in second and third infections, or resumption after relapse. The proposal to use sulfonamides as a species of prophylactic routine, to give them on suspicion either in the presence of clinical without laboratory evidence or even on complaint that the person to whom they are to be given is a source of infection without a proved case, has a serious aspect here. Already there are medicolegal decisions to the effect that giving sulfonamides for conditions in which they are not recognized as effective (such as colds) and producing complications established a presumption of malpractice. What will happen when a smart lawyer gets, in one sense or another, a good case of sulfonamide reaction following prophylactic or therapeutic test administration of the drug?

SOME PROBLEMS OF PROPHYLAXIS

The field of prophylaxis, experientially one of the most productive and promising in venereal disease control in wartime, is, investigatively speaking, the least exploited and most chaotic of them all. The amazing effectiveness of station prophylaxis routinely enforced shows that we have something incomparably useful, with no clear idea of what makes it so. With respect to prophylaxis, realism has had a hard time being heard. Preexposure prophylaxis without control of the alcohol factor is not worth the paper on which it is described. I have had a physician after a get together find in his pocket the condom he put there with the best of intentions. If condoms can be sold to women, and they can be induced to insist and assist, they may join the really fighting front. In this jumble of "theys" I am reminded of the answer given me by a top notch expert on the problem. He said condoms were not used where they were needed and would never be popular because they spoiled the act "like washing your feet with your sock on." I do not recall a set of film or other prophylaxis instructions which says or shows that the lubrication should be inside as well as outside the condom. Logically protection of any sort should be preexposure and not postexposure, and if there is to be any hope that intelligence and not emotion will dominate its use, it should be applied well in advance and have both penetrating and staying power rather than mere momentary mechanical virtues. It should be put on like a cloak of darkness before sallying forth on questionable adventure. The ideal prophylactic is not beyond the bounds of possibility. It should be a penetrating, inconspicuous or even colorless substance or solution like some of the dyes or their leukobases if active, which can be fixed in the skin or mucous membrane for a considerable period, applied over a week end in which heaven or hell knows what may turn up. Anything to be put in or on at the time has so large a margin of objection that it cannot be expected to meet the problem. The casualness and opportunism of much current sexual exposure today rules out even a lubricating oil or jelly. Preexposure prophylactics to the user's way of thinking have contraceptive effect, and it is largely this rather than any idea of preventing disease that actuates the use of the condom. Before preexposure prophylaxis can really be worked out, an adequate technique of animal study (preputial sac of the male rabbit) must be evaluated. Finally I hope not to be taken too seriously when I say that I have wondered whether the Castellani carbolfuchsin paint, astonishingly effective as a bacterial inhibitor in other infections, did not deserve a trial, of the vivid color of a mandril's rump, and not too irritating if not too often applied, it should displace the pink condom over night on esthetic grounds alone.

Postexposure prophylaxis, enforced impartially if it were enforceable, would be almost the answer, were it not for the time factors. But we all know that it is not going very fast as a selling proposition for voluntary use. Closing the gap between a 1:3, 1:5 and even 1:9 ratio between prophylaxis taken and exposures made, is more than an administrative task. As the venereal infections become less and less serious in the light of their increasingly easy cure, gonorrhea, I am credibly told, is becoming a popular form of vacation from the strenuities of camp life. Washing facilities, the probable crux of effectiveness of all present postexposure methods, are too difficult of prompt access even when hospital receiving wards and police stations shall have

been universally enlisted. The research indications are, then, again for an emulsion based, penetrating and washing preparation, pleasantly scented, which can be put on and left on, without the use of water or basin, until the next shower. Here is where the as yet insufficiently studied penitents count, for any one who has ever watched a clock for three not to say five minutes knows that only absolute time clock supervision of rubbing or washing brings full observance, and the boredom alone, not to mention any discomfort, tends against repetition. In fact, it is sharply said of most postexposure prophylaxis that one must be slightly drunk to see it through. Once more, unreported experimental studies offer preliminary hope of discovering a single chemical agent which dissolved or suspended in an appropriate penetrant vehicle will be effective at once against the four major diseases, including venereal lymphogranuloma.

THE PROBLEM OF MORALE IN VENEREAL DISEASE CONTROL

We are confronting a morale problem in this war that has important and serious elements of difference from the last. Scientific discoveries may and in fact are already enhancing the effect of a general loosening up of sex standards. As evidence of the loosening we witness a shift of the infection source from professional prostitute to casual which has delayed and even defeated the approach to control at a number of important points. We find the girl friend or pickup performing her uncertain offices without cost, which confounds the police attack on prostitution, and we find among women and girls of the most unexpected types an almost avid desire to show the boys a good time. Solicitation seems to be climbing to unheard of proportions in many cities, and the dating mechanism developed during peace is superfunctioning in time of war. Some peculiarities of our national effort are important too. We are concentrating troops overwhelmingly in the South, in areas where both white and colored races have a phenomenally high incidence of venereal disease. The color line is thinning, drawing on the Negro reservoir of infection, the highest in the country. Transportation has done things to a peripheral cantonnement control which worked in the last war but is far less effective in this. The population as well as the armed forces is on the move, and civilians, equally with the soldier and sailor, are swept into the morale wrecking effects of change, break-up of home and stabilizing influences, loneliness, unrest. Liquor has been less effectively dealt with, later in the game, than in the last war. And now scientific discovery, the one day cure of the malignant but often effective fear producing deterrents of disease, is knocking the props out from under our platform.

Where shall we turn in a situation like this, if not to rediscovery of old truths and their reemphasis in education? The scanty grace now accorded a clean way of living, continence, discussed in five words followed by a but, in the current official instructional films, only stresses to me the more intensely the need, the imperative need, for a moral rejuvenative and positive force to replace a growing cynicism in this whole business. Perhaps it is intended to leave all that to the chaplains. Earnest and effortful though they may be, they will fail. The control of venereal disease, the clean conduct of the sexual life, cannot be made effective by ecclesiastically coated pills. It is a man to man and day to day affair, and it is the business of the com-

manding personnel from squad corporal to colonel and general on land and up the navy staff to the topmost admiral on the sea. The medical officer in particular owes the morale side of this problem an unshrinking and wholehearted allegiance. The man on whom it fell to summarize the record of the American Expeditionary Forces in the last war I think is not too incorrectly quoted as saying that the sense of being set apart for a great destiny raised the proportion of continence in our armies far above the expectancy for armies generally, and that continence, and not the barbed wire of Sainte Nazaire, kept down our rates. If ever there was a day when the bodies of men, equally with their souls are set apart for a great destiny, this day is it. I hope that the old stagers of today who, like myself, have slogged through the mud and squinted painfully through the dust of this campaign to make man master of his sexual destiny will through your mingling of spiritual powers with your physical armament at last see the coming of the light.

CARCINOMA OF THE PROSTATE

IMMEDIATE RESPONSE TO BILATERAL ORCHIECTOMY, CLINICAL AND X-RAY EVIDENCE

EDWIN P. ALYEA, M.D.

AND

A. F. HENDERSON, M.D.

DURHAM, N. C.

Twenty-five years ago Dr. Charles Mayo said "No matter what you do for carcinoma of the prostate, you do the wrong thing." Today this is not true. We can relieve the urinary obstruction by transurethral resection, cause regression of the primary tumor by irradiation and relieve the metastatic pain in most cases by high voltage roentgen therapy to the spine or glandular focus. Further relief from pain, if necessary, can be afforded by spinal injection of absolute alcohol or section of the sensory tracts of the cord. Within the last two years a new approach to therapy for carcinoma of the prostate has been offered. This paper is not a comprehensive symposium on endocrine therapy for carcinoma of the prostate. The various phases of this subject have been discussed in other papers. The relationship of glandular products to activation of prostatic epithelium and carcinoma of the prostate has been thoroughly covered in many papers reported during the last few years.

We present a brief report of the immediate results of castration in 40 cases of carcinoma of the prostate. What the later results will be we do not attempt to prophesy. All but 1 patient has been contacted within the last month. Carcinomatosis was responsible for the death of only 1 of the 4 patients who died. This is the only unsatisfactory case in our series. This low mortality in such a group, during a whole year, is significant. It would certainly have been much higher under the usual routine therapy.

The immediate result with all these patients was almost miraculous. Their general well being and energy at once improved, their appetites picked up and they gained weight. One man gained 50 pounds.

From the Urologic Division of the Department of Surgery, Duke University School of Medicine and Duke Hospital.

Read in the Symposium on Treatment of Carcinoma of the Prostate Gland before the Section on Urology at the Ninety Third Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1942.

(23 Kg) in one year, another 35 pounds (16 Kg) and so on. Eight of these men were bedridden and 3 others could walk only with crutches. All of them were up and about without assistance in ten to fourteen days. Two of the patients had edema of the extremities, most likely from glandular metastasis. The edema in

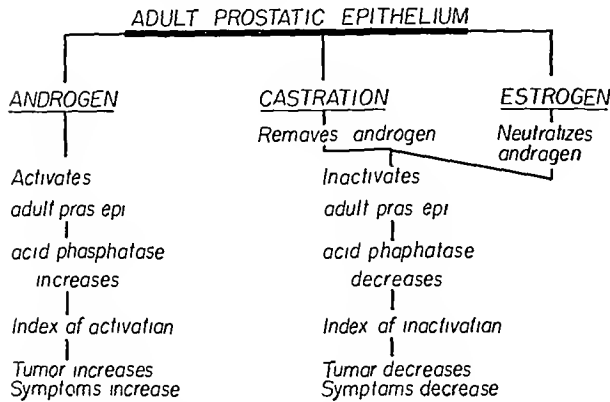

Fig 1—Relationship between adult prostatic epithelium and hormones

1 of these subsided entirely, and partially in the other following castration. Eighteen of these patients were in complete and 22 in partial urinary retention. All but 4 had a transurethral resection performed on them for relief of their obstruction.

One of the striking features of their improvement was the rapid relief of metastatic pain, usually within twenty-four to forty-eight hours after castration. One patient whose condition was unsatisfactory returned, after eight months of relief, with pain and extension of the tumor growth. This relief of pain is most gratifying, and if such therapy had no other value, this one thing would warrant its use. How long this relief will last, we do not know, but time will tell.

Castration was performed on 14 patients who showed no evidence of metastasis. We hoped by this, in addition to causing regression of the primary growth, to

Fig 2—A osseous metastasis of carcinoma of the prostate note hazy fuzzy soft osteoblastic response of new bone growth throughout pelvis especially in superior ramus of pubis and in obturator foramen. B same after castration note bone healing sclerosing and clearing of bone detail, approaching normal bone.

retard or prevent the spread of the tumor. Seven of these have had x-ray examination recently and as yet none show metastases. The first case is now of one year's duration. It will, of course, take three to five years before this evidence will be forthcoming. One might compare this with sterilization for carcinoma of

the breast. Taylor¹ thought that it did not alter the course of the disease. On the other hand, from the standpoint of endocrine therapy such a comparison is perhaps unwarranted.

The increase of serum acid phosphatase in carcinoma of the prostate is most interesting. Huggins,² Gomori,³ Gutman,⁴ Woodard⁵ and others⁶ have discussed this thoroughly. Suffice it to say that acid phosphatase is found in largest amounts in the adult prostatic epithelium and carcinoma of the prostate, which is a tumor composed of this cell. When metastasis takes place, the tumor cells are expressed into the blood stream and lymphatics and cause a rise in the serum acid phosphatase. Therefore this is an indication of tumor or adult prostatic epithelium activity. The alkaline phosphatase is also increased in these cases. This is dependent on bone defense reaction to the tumor. This series shows that of 17 patients with metastasis 10 had normal serum acid phosphatase and 7 elevated. The King and Armstrong method was used in all, and 4 units was taken to represent the normal. Others have suggested anywhere between 3 and 6 units as normal.

Fig 3—A osteoblastic response to metastasis throughout pelvis especially superior ramus of pubis and into obturator foramen. B after castration sclerosis and clearing of new bone.

This may be a distinct aid in differential diagnosis and proved to be so in 2 of our cases. Certainly, if the serum acid phosphatase is over 10 units it is almost surely indicative of carcinoma of the prostate. However, as we see in this series, it may be perfectly nor-

mal with or without metastases. The highest report we have had is 180 King and Armstrong units in a patient with a tremendous tumor mass in the pelvis. This would agree with the theory that the enzyme is dependent on the tumor cells for its activation. The alkaline phosphatase determinations showed that they too may be either normal or elevated, but if metastases are present, they are more apt to be elevated.

The relationship between gonadotropic substance and prostatic epithelium is shown in figure 1. Androgen activates the prostatic or tumor cells. This activation may be measured by the serum acid phosphatase. Castration and the removal of the androgen causes a

drop in the index of activation, acid phosphatase and we see clinical signs of regression of the tumor. Similarly, neutralization of the androgen with estrogen causes the same response. In our series 7 of the 18 patients with normal acid phosphatase showed a drop in the acid phosphatase to even lower normal figures after castration. Seven of the 8 with elevated acid phosphatase showed a drop to near normal levels. The 4 on diethylstilbestrol therapy showed a similar phosphatase reduction.

Clinical evidence of regression of the tumor is further indicated in the patients' relief of obstruction. Four of these patients had no operation for removal of the obstruction. The others had transurethral resection. All of the 4, including 2 in complete urinary retention, are voiding satisfactorily and have needed no operative treatment for the obstruction. This must mean that the gland receded enough to relieve the obstruction. Rectal examination in every 1 of the 30 patients who returned for examination showed considerable reduction in size and softening of the gland. Many were softer than normal and it would have been impossible to diagnose carcinoma of the prostate at this time. The case which came to autopsy showed a normal size prostate and seminal vesicles. The pathologist remarked that he would not have been suspicious of carcinoma of the prostate at all from the gross appearance of the gland. A comparison of the microscopic pathologic section of the prostatic tissue before castration with that obtained at autopsy showed decided change, the latter section showing pronounced fibrosis, replacing glandular tissue. Furthermore, chemical analysis of the acid phosphatase in the prostate showed only 8 units per gram of tissue, compared with the normal amount of 500 to 2,000 units reported by Gutman. This is again direct evidence of the definite regression and inactivation of the prostatic epithelium. A complete report of this case is forthcoming.

Further direct evidence of improvement is shown in the clearing of the urinary infection which most of these patients have before and after transurethral resection. It is customary for the infection to remain for many weeks or months after resection for a carcinoma of the prostate. Curiously enough, almost all patients returned

Fig. 4—Pulmonary metastases for carcinoma of the prostate two and a half months after castration. The lung is entirely clear with no metastases present.

with sparkling clear urine. This shows that the regression of the gland was such as to do away with any residual urine. Five of our patients had a history of preoperative or postoperative recurrent attacks of hemorrhage. One had had such profuse hemorrhages that he had had, elsewhere on two occasions, suprapubic cystotomy with packing of the vesical orifice. Since castration none of these patients have had any bleeding at all. All of these phenomena are indications of regression of the primary tumor following castration.

The objective signs of improvement and tumor regression have been most interesting to us. The usual evidence of metastasis of carcinoma of the prostate is seen in the bones of the lumbar spine and pelvis. The reactions are both osteolytic and osteoblastic in type, and the latter is by far the more frequently seen by us. This reaction is the result of the defense response of the bone to the tumor (figs 2 A and 3 A). The new bone laid down is soft and appears in islands scattered here and there. New bone growth extending out from the ischium and pubis into the surrounding soft parts is often seen. In the roentgenogram it appears as soft, fuzzy and hazy outlined bone, similar to that of sarcoma. It does not have the dense, sharp and distinct cancellous character of healthy bone. Following castration there is a striking change in this picture. There is a distinct smoothing and sclerosing of bone detail approaching more normal type bone. The reaction is similar to that seen in postirradiation healing (figs 2 B and 3 B). This is indirect evidence of regression of the tumor in the bones and occurred in all but 3 of our cases showing metastasis. One showed decreased density, 1 had no change, and 1 showed apparent extension. Whether this is a real extension or simply an increased density of the tumor areas already present is difficult to say. In our series in fourteen metastases were found in the lumbar spine and pelvis, seven only in the pelvis, none only in the spine, five in the ribs and 4 in the lungs.

Of even more interest to us has been the disappearance of the metastatic tumor from the lungs. Our series shows 4 cases with pulmonary metastases. This relatively high percentage is probably best explained by the fact that for the last year we have taken routine roentgenograms of the lungs of every patient with carcinoma of the prostate we have had. If this is done in other hospitals, it will be most interesting to see if this 10 per cent is the usual frequency encountered. Two of these cases showed multiple small milary type metastases (fig 4). Careful differential diagnosis between tumor, sarcoid or moniliasis was necessary. The patients had no symptoms or physical signs or the usual history of sarcoid or moniliasis. They cleared up far too quickly on no specific therapy. Internists and roentgenologists especially interested in these diseases were consulted. They all agreed that there was no question but that it was neither sarcoid nor monilia-

Fig. 5—Pulmonary metastases from carcinoma of the prostate eight months after castration. Note rounded nodules in lower and middle lobes. Lungs clear with no metastases.

sis but must be metastatic carcinoma. One of these patients subsequently died, and the substantiation of the diagnosis was made at autopsy. Several small metastatic areas of tumor were found scattered throughout the lungs. The other 2 cases showed typical round isolated metastatic nodules, for the most part in the lower lobes (fig 5). This is the part of the lungs in which one would expect to find the metastases. Roentgenograms in these cases two and a half months after castration, and in 1 case five months later, showed that the metastatic nodules had disappeared. To our knowledge this is the first time this phenomenon has been demonstrated. In the roentgenogram of the bones we see the indirect evidence of regression of the metastatic tumor and in the lungs we see the direct evidence of the tumor itself disappearing. This evidence of the antitumorogenic action of glandular preparations is most interesting and stimulating to further researches.

The effectiveness of diethylstilbestrol in carcinoma of the prostate has been tried in a few cases in our clinic. In all the cases there was a regression of the primary growth and relief of pain. But the results were not as striking as following castration. These will be discussed more in detail in another paper. Diethylstilbestrol is certainly indicated in cases unrelieved by castration, in recurrence of symptoms after castration and when castration is refused.

Two operative procedures have been used by us for castration. In one small group we left the epididymis in place and peeled the testis off from it. This procedure leaves a small rounded inflammatory mass in the scrotum which some think advantageous from a psychic point of view. In the other group the testis and epididymis were both removed. We much prefer the latter procedure.

SUMMARY

1 During the past year 40 patients with carcinoma of the prostate have been castrated.

2 A follow-up in all but 1 case shows a low mortality.

3 The immediate clinical results in all cases was most encouraging.

4 One patient had a relapse and extension of the tumor after eight months of comfort.

5 The subjective signs of improvement after castration are increase in appetite, well being and energy, relief of metastatic pain, relief of urinary obstruction, disappearance of infection and the stopping of recurrent hemorrhage.

6 Objective clinical and laboratory signs of improvement and regression of the tumor after castration are lowering of the serum acid phosphatase, x-ray signs of bone healing at the site of the metastases and the disappearance of pulmonary metastases.

7 Diethylstilbestrol causes a response similar to castration but not of the same degree. We favor castration first and reserve diethylstilbestrol therapy for those who show evidence of extragonadal hormone activity or refuse castration.

CONCLUSION

Our series of 40 cases of carcinoma of the prostate in which bilateral orchiectomy has been done shows remarkable immediate favorable results. We wish to emphasize again that we do not prophesy what will happen to these patients after the first postoperative year.

THE DIAGNOSIS AND TREATMENT OF EARLY CARCINOMA OF THE PROSTATE

C. D. CREEVY, M.D.

MINNEAPOLIS

Carcinoma of the prostate deserves the close attention both of the medical profession at large and of all urologists, because in existing circumstances its incidence is increasing and its prognosis is bad. Thus, Moore¹ found it in 21 per cent of autopsies on men past 41 and Duff² reported that its frequency as a cause of death among male policyholders of the Metropolitan Life Insurance Company rose from 0.8 per hundred thousand in 1917 to 3.7 in 1928. This rise seems to be due, not to a heightened individual susceptibility to cancer, but to a striking increase in longevity. For example, the number of men living past the age of 65 doubled in the United States between 1911 and 1935, between 1911 and 1941 life expectancy of males at birth increased from 48.2 to an estimated 63.4 years.

Fig. 1—Relation of carcinoma to coexisting benign hypertrophy of the prostate.

Despite this increase, early prostatic carcinoma continues to be a clinical rarity. As evidence thereof, Young³ regarded but 3.4 per cent of 1,040 cases as suitable for a radical operation aimed at cure, while Barringer⁴ has stated that in only 4.5 per cent of 352 cases did carcinoma of the prostate appear to be a local disease. Further, Bumpus⁵ found metastasis to bone in 24 per cent of 1,000 cases at the initial examination, and Ferguson⁶ found them in 30 per cent of his series. Kahler⁷ could detect some evidence of metastasis in 51 per cent of patients at autopsy.

From the Urological Division of the Department of Surgery, the University of Minnesota Medical School.

7 Kahler, J. E. Carcinoma of the Prostate Gland. Pathologic Study. *J. Urol.* 41: 557-574 (April) 1939.

There are many reasons for late discovery of the disease. First, prostatic carcinoma causes no symptoms until it interferes with urination or produces pain by local extension or metastasis. Second, three fourths of the cases (Moore) arise in the posterior lamella at a relatively great distance from the urethra, hence obstruction develops late. Third, the average prostatic carcinoma grows slowly. As evidence, Chwalla⁸ had 2 patients who lived eight and nine years respectively after simple cystostomy, and Crenshaw⁹ once made the diagnosis thirteen years before obstruction to urination necessitated transurethral resection, tissue from which confirmed the diagnosis. Fourth, about 8 per cent of prostatic cancers (von Illyes¹⁰) develop within spheroïds of benign hypertrophy which hide them from the examining finger. Fifth, most elderly men regard a certain amount of urinary difficulty as an inevitable accompaniment of advancing years and delay medical consultation until severe retention or pain appear. And last, many physicians are not thoroughly aware of the serious significance of isolated hard nodules in the prostate. This fact is directly traceable to the pessimistic view of prostatic cancer held by most urologists.

Thus we may conclude that carcinoma of the prostate is likely to be recognized early only if an alert physician makes a rectal examination in the absence of urinary symptoms, if a coexisting benign hypertrophy causes retention of the urine while the carcinoma is still localized, or if a pathologist finds a "concealed" carcinoma in material resected or enucleated for supposed benign hypertrophy.

Fig 2—Prostate covered by rectourethralis muscles and both layers of Denonvillier's fascia

The earliest carcinoma of the prostate which is recognizable clinically appears as a small stony hard, irregular, poorly circumscribed nodule and does not

produce any symptoms, although obstruction to urination may be due to an associated benign hypertrophy. Not all hard nodules in the prostate are cancerous, and careful study may be required to determine their nature. Prostatic tuberculosis is usually accompanied by a story

Fig 3—The apex of the prostate has been freed and turned down and the anterior wall of the bladder incised

of urgency and frequency of urination, and pyuria. Prostatic calculi are often crepitant and are visible in a roentgenogram of the pelvis, although one must remember that cancer and calculi may coexist. Occasionally such a film, made of a patient with an apparently "early" neoplasm, will demonstrate silent metastases to bone. An elevation of the phosphatases in the serum may reveal that a suspicious lesion in bone is actually a metastasis. If both studies yield normal results, one may try a course of local heat (hot rectal irrigations, Elliott therapy, diathermy) during which a nodule of inflammatory origin may disappear.

If the nodule persists, biopsy is indicated, and it is here that aspiration biopsy should be of great value. Although Ferguson has found it accurate in 86 per cent of his cases of prostatic carcinoma, Barringer¹¹ has recently estimated its accuracy at 50 per cent. My experience is more like that of Boyd,¹² who called it disappointing in the small lesions. Biopsy with the resectoscope is also satisfactory in advanced lesions, but to secure an adequate specimen in an early neoplasm localized in the posterior lamella (fig 1) requires an unusually thoroughgoing resection which is hard to justify in the absence of symptoms, particularly since it leaves an infected field not well suited for a radical operation shortly thereafter. In my experience biopsy can be done satisfactorily in early cases only through a perineal exposure under direct vision.

Those who favor the "wait and see" policy will object to open perineal biopsy, arguing that the chance of cure by any method is too small to justify it, they prefer simply to observe the patient with an early carcinoma which causes no symptoms and will deal with complaints as they arise by the administration of endocrine preparations, castration, transurethral resection or irradiation. While there is much to justify this widely held attitude, it does not lead to cures.

Those who are more optimistic may implant radon in the nodule and perhaps employ therapy with the high voltage x-rays. Since reactions are often severe, and authenticated cures few and far between (Barringer had two in 352 cases), the wisdom of this procedure is debatable. Its value in early cases cannot be determined for lack of reliable criteria as to what would happen if this form of treatment was not employed, i. e. no one knows how long it would be before symptoms appeared.

Castration as developed by Huggins¹³ is, and will continue to be, very difficult to justify to the patient without symptoms, and it seems to have no place at present in the treatment of early cases without pain although often brilliantly successful in late cases as a palliative measure. A patient who is relieved of

continued administration are not yet known, and because the duration of its beneficial effects remains to be determined. It appears to hold great promise, and it demands long and painstaking study. Like castration, it has produced striking results in late cases.

Fig 5—Anastomosis of membranous urethra to base of bladder and closure of defect in bladder

Fig 4—Ligation of vasa and removal of vesicles after separation of the bladder from the prostate

severe pain by castration will view its untoward effects tolerantly, while one who had no symptoms in the first place is likely to be greatly disturbed by them.

It is too early to try to evaluate the use of estrogens in the early cases, both because its by-effects after long

(Herbst,¹⁴ Kearns and his collaborators¹⁵) The effectiveness of both these methods, particularly in relieving pain, tends to support the "wait and see" school of thought.

Transurethral resection, despite its immense value as a palliative measure, cannot be mentioned as offering any hope of cure. The same may be said of enucleation, whether perineal or suprapubic, although an occasional small carcinoma completely enclosed within a spheroid of benign hypertrophy may thus be cured. In 96 cases collected from reports by Cunningham,¹⁶ Schmidt and Hirsch,¹⁷ von Illyes¹⁸ and Bugbee¹⁹ there were 26 per cent of two to five year "cures." One can scarcely speak of cure in less than ten years.

The only method which can be said at present to offer a definite prospect of cure is radical perineal prostatectomy, so long advocated by Young. Lewis¹⁹ has reported "just under 50 per cent of five year cures" in 115 cases of Young and his associates. In doubtful cases the operation should begin by exposing the prostate, excising the nodule with a diathermy loop and submitting it to a competent pathologist for study by "fast frozen" section, if carcinoma is found, total prostatectomy is carried out at the session.

It is important to memorize carefully the exact location of a small lesion beforehand, since for some obscure reason it may be difficult to locate with the patient anesthetized. The operation is carried out through Young's approach (fig 2) and is not difficult technically unless the perineum is quite thick, the gland large or the pubic arch narrow. The urethra is divided at the apex of the prostate, which is then reflected backward to expose the vesicoprostatic juncture (fig 3). The bladder is opened just above it by a transverse incision which continues clear around the periphery of the prostate. The ampullae of the vasa are divided and ligated, and the vesicles dissected out (fig 4). The cut edge of the urethra is joined with mattress sutures over a Foley bag to the cut edge of the bladder, the remainder of the opening in the bladder is closed longitudinally by a running stitch (fig 5).

Convalescence is usually smooth and short, probably because there is no prostatic bed to become infected. The last 3 patients have left the hospital in twelve to fourteen days with normal control of urination.

There are several arguments against the use of this operation. The mortality is as high as 10 per cent. There is a very definite risk of incontinence, permanent incontinence having resulted in 2 of 10 cases at the University Hospital. One patient loses a few drops during exertion, and 1 died of operation so that control could not be determined, but 6 had normal control.

Removal of the seminal vesicles removes the means of orgasm, but this is not an insurmountable objection in elderly men.

It can be argued that the very patients in whom the operation is indicated might live, as did Crenshaw's, in comfort for many years without operation. This admittedly cannot be settled.

The chief obstacle to the satisfactory use of radical perineal prostatectomy is its low rate of applicability, which can be overcome only by a campaign of education designed to lead to early detection of prostatic carcinoma.

Before defending the method, one may well ask whether any attempt to cure any cancer in any organ is defensible. If the answer is yes (as it certainly is) then radical perineal prostatectomy is worthy of a widespread trial, especially since it carries a better chance of cure than any other method. Moreover, it very nearly eliminates the danger of that subsequent obstruction to urination which is the bane of all other methods. Its mortality is certainly reducible by further experience to a very low level (our one death was due to infection in the presulfonamide era). When it is argued that the operation is too formidable for an old man, one must remember that an old man may suffer just as keenly as a young one and has less to lose.

SUMMARY AND CONCLUSIONS

- 1 The number of cases of carcinoma of the prostate is increasing, not because of increased individual susceptibility, but because of increasing longevity.
- 2 Its prognosis is poor.
- 3 The early case can be recognized if every small hard nodule in the prostate is subjected to careful study, including biopsy.
- 4 Aspiration biopsy is least useful where most needed, i. e. in small nodules of doubtful character.

5 Treatment may be symptomatic, but radical perineal prostatectomy alone offers any real hope of cure, although its rate of applicability is low.

6 The role of endocrine preparations in the therapy of the early case offers interesting possibilities.

7 Widespread trial of radical perineal prostatectomy should be made in properly selected early cases.

TRANSURETHRAL RESECTION OF MALIGNANT LESIONS OF THE PROSTATE GLAND

GERSHOM J. THOMPSON, MD

ROCHESTER, MINN.

The attending physician may be asked many difficult questions by the patient afflicted with a malignant process of the prostate gland.

Because of the nature of the disease, the patient generally is free of symptoms until the lesion is rather well advanced. Often symptoms of urinary obstruction, such as diminution in the size and force of the stream, and urinary frequency or nocturia, are the first indications of the disease. Less frequently pain caused by skeletal metastasis or loss of weight and anemia without the slightest urinary distress are the only signs of the disease. In either case complete surgical extirpation of the lesion is practically always impossible. Until Huggins and his co-workers¹ discovered that bilateral castration usually would bring about regression of the local malignant process and of generalized metastasis, surgical procedures, if indicated at all, were at best purely palliative for 95 per cent of all patients afflicted with prostatic carcinoma.

Most surgeons who have advocated radical perineal prostatectomy also have freely admitted that the procedure can be utilized in only 5 per cent of cases or less. They make a plea for earlier diagnosis, calling attention to the desirability of frequent rectal examination, especially in men beyond the age of 50. Every physician will wholeheartedly agree with this recommendation in the hope that very small neoplasms which have caused no symptoms may be discovered and appropriately treated.

Radical operations in this carefully selected group, according to the reports of Colston² and of Smith,³ achieve five or more years of survival for half the patients treated. Thus, of the selected 5 per cent of all patients who have prostatic cancer, half, or about 2.5 per cent for whom such a diagnosis is made, survive radical operation for five years.

The outlook, then, would indeed seem discouraging if it was forgotten that the average age of the patient at the time of discovery of the disease is about 70 years. True enough, a few patients suffer from prostatic cancer in their early fifties, but the great majority are at an age at which life expectancy, because of other types of coexistent degenerative disease, is not great, hence the

problem resolves itself into the question as to which type of treatment can be employed at the least risk and still provide the greatest degree of comfort. The declining years of these men, most of whom are grandfathers are perhaps among the most enjoyable of their lives. For this reason the chance of shortening their lives or of rendering them incontinent of urine must be weighed carefully, it must be remembered that even in the smallest lesions metastasis beyond the confines of the prostatic capsule may already have occurred.

The great tendency for carcinoma of the prostate gland to metastasize early has been demonstrated by extensive treatises on pathology by Moore,⁴ by Rich⁵ and by Kahler.⁶ The work of these men was recently substantiated by Baron and Angrist,⁷ who studied the incidence of occult adenocarcinoma of the prostate gland among men beyond the age of 50. These workers studied 50 cases in which the prostate gland in its entirety had been obtained at necropsy. They stated that

no attempt was made to select prostates with areas arousing suspicion. The general size of the prostate was noted and, to evaluate the accuracy of the gross diagnosis, an attempt was made to pick out areas in the gross specimen which suggested induration or other gross criteria of carcinoma. In only 1 case of the entire series of 50 was the area suspected of carcinoma found to have been chosen accurately.

Using the criteria which we have outlined in a foregoing section, we found carcinoma in 23 of the 50 prostates, an incidence of 46 per cent. In 9 of these 23 glands the carcinoma was in the lateral lobes and in 4 in the posterior lobe. In the remaining 10 the neoplasm either was too large to allow determination of the site of origin or occurred at the site of junction of the lateral and posterior lobes, invading both. This differs from the widely accepted concept that carcinoma usually originates in the posterior lobe.

Results of this study indicate that carcinoma of the prostate gland cannot be detected early enough by any clinical method of examination now known to make it possible to effect cure by radical surgical extirpation.

Kahler in his study found a very high incidence of perineural lymphatic involvement, even in cases in which the lesion was extremely small. In fact, in searching for extension to the perineural lymphatic vessels with the low power objective he found such involvement in the same microscopic field as that which included the tumor in all cases except 13 per cent of grade 1 tumors and 15 per cent of grade 2 tumors. Furthermore he found that, in 51 per cent of cases in which the tumors had been recognized clinically or grossly, distant metastasis was demonstrable at necropsy.

During the past ten years at the Mayo Clinic we have not employed radical perineal prostatectomy. In our opinion the evidence at hand clearly indicates that when carcinoma of the prostate gland has developed sufficiently to cause urinary obstruction the disease has spread through the perineural lymphatic vessels and cannot be completely eradicated by any surgical procedure.

It has been our belief that complete surgical removal of even the smallest lesions is impossible. Therefore in considering a case, for instance, in which a tiny

nodule with only a suspicion of malignancy exists it has seemed to us best to advise either no treatment or, at the most, a course of roentgen therapy. In many instances only periodic observation has been advised, and practically every suspected lesion that has been observed has remained small and the elderly patient has succumbed after a number of years to some other disease. Such an attitude might be questioned, however, we feel that the work of Moore, Rich, Kahler, Baron and Angrist, in addition to the clinical experience we have obtained by having observed over a period of years many such patients, justifies this stand.

Bumpus⁸ in 1922 reported a large series of cases in which radium therapy was instituted. The results of such treatment did not justify its continuance, as he later emphasized. Bumpus⁹ in 1930 called attention to the great value of transurethral resection as a means of palliation.

It is our present attitude at the Mayo Clinic that transurethral resection which adequately removes all the obstructing tissue, combined with bilateral orchiectomy¹ (or, if the patient refuses this, irradiation or the administration of diethylstilbestrol), offers the patient a far better prognosis than does any radical procedure. This scheme of treatment is accompanied by much less risk to life than is the radical operation and offers almost certain assurance that control of micturition will be perfect.

MATERIAL STUDIED

It seems appropriate, in defense of the aforementioned attitude, to present a statistical study of a group of 887 cases of malignant neoplasms of the prostate gland in which transurethral resection was performed during the interval 1924 to 1941 inclusive. Practically all the operations were done in the last ten years, only 20 of the 887 operations having been performed prior to 1932. Special attention will be directed to a group of 334 patients who were operated on prior to Jan. 1, 1937, since in these 334 cases it is possible to obtain survival figures of five years or more. In all the cases included there was pathologic confirmation of the diagnosis by microscopic examination. In 17 cases a definite clinical diagnosis of carcinoma of the prostate gland had been made but there was no histologic diagnosis of malignancy, and these 17 cases therefore are excluded from the series in this study.

I wish to make clear the fact that this group of 887 is composed only of patients who had definite symptoms of urinary obstruction. A large group of patients who had a malignant lesion in the prostate gland but no urinary symptoms is excluded. These patients were treated, if they were treated at all, by irradiation.

AGE OF PATIENTS

Reference to table 1 will show that the mean age of the patients in this series of cases was 69.5 years. Only a few were less than 50 and a considerable number were more than 80 before their carcinoma caused symptoms which required relief by operation. In the light of Baron and Angrist's observations as to the incidence of occult carcinoma, it seems likely that many of these men had the neoplasm for at least ten years prior to operation. We have seen from time to time many men in whom a very small nodule, regarded as being suspiciously malignant, was discovered eight to ten years

or more prior to the onset of urinary symptoms. I do not think that any great number of these patients could have been cured by a radical operation at the time they were first examined.

DIAGNOSIS

The only certain method of diagnosis is microscopic examination of tissue removed either at operation or by biopsy. Aspiration biopsy has been recommended by some. This is a very uncertain procedure and it seems likely that in any case in which the lesion is large enough to be found with a needle passed through the perineum under the guidance of a finger in the patient's rectum the malignant process has already progressed to a stage in which complete removal is impossible.

Any prostate gland which is very firm in consistency should be regarded with suspicion. However, not all malignant glands are firm nor are all which are firm malignant. Careful examination of the edges of the gland, especially of that portion on the lateral border just within the anus, is important. If the bladder is distended, coincident edema may be sufficient to mask the malignant area. Reexamination after a day or two of drainage by catheter is therefore desirable.

The making of a plain roentgenogram of the area of the kidney, ureter and bladder which also includes the ischium and upper ends of the femurs, often will reveal

metastasis which was unsuspected on the basis of the clinical history. Other data with reference to diagnostic points, especially those obtained by cystoscopic examination, have been discussed in a previous publication.¹⁰

OPERATION

Transurethral resection was performed with either the Braasch-Bumpus, Stern-McCarthy or Thompson resectoscope. In by far the majority of cases the last named instrument was used. The removal of all obstructing tissue was the aim of the surgeon in each case. This of course does not mean removal of all malignant tissue, for, as previously stated I do not think this is possible by means of any type of operation. However, adequate removal of all tissue encroaching on the neck of the bladder and the prostatic urethra is readily accomplished by transurethral resection. An almost normal urethral contour can be reestablished by this procedure, as can be shown by reexamination many months after operation. At that time perfect healing of the surface is apparent, the statement which has been made that a malignant prostatic urethra does not heal is erroneous, according to my experience. If the operation is properly performed the voided urine will be microscopically negative within a few weeks postoperatively in a high percentage of cases. Ease and comfort in voiding, with excellent immediate control, is the rule. Only exceptionally is there any urgency, and very rarely does permanent incontinence result.

In most instances in which postoperative incontinence occurs it is caused by trauma incidental to introduction of the resectoscope. Careful dilation of the urethra with sounds before the instrument is introduced will greatly lessen the hazard of incontinence. In exceptional cases fixation of the external sphincter by extension into it of the malignant process may result in

TABLE 2—Amount of Tissue Removed

* Concerning 50 patients there was no record of the amount of tissue removed.

incontinence. If this involves the entire sphincter the damage may be irremediable, however, in several instances I have removed the proximal half of the sphincter and have thereby restored continence for a considerable interval.

In my opinion based on the performance of cystoscopic examination of a number of patients who have undergone radical operations elsewhere prior to coming to the Mayo Clinic, a much better appearing prostatic urethra results from transurethral resection than from other types of operation. It is necessary, of course to remove all encroaching nodules. Incomplete transurethral resection is no better than a gouging, tearing procedure of any sort. With a resectoscope tissue can be planed down so that a smooth, uninterrupted flow of urine through the neck of the bladder and prostatic urethra is possible for many months or even years. In table 2 is shown the amount of tissue removed. In many cases very substantial amounts were excised, the mean weight being 17 Gm.

PATHOLOGIC ASPECTS

As previously stated in all the cases included in this series histologic confirmation of the diagnosis was obtained. It is interesting to note that during the interval of 1924 to 1941 inclusive, in only 17 instances in which a definite clinical diagnosis of carcinoma was made did resection fail to include tissue which was

TABLE 3—Grade of Malignancy

	Patients	Per Cent

* In 6 cases the grade was not noted.

malignant. This refutes the statement that transurethral resection often will remove only benign tissue and leave substantial amounts of malignant tissue in the posterior portion of the prostate gland. Resection which is done in that manner will of course provide only temporary benefit if indeed any.

In table 3 is shown the grade of malignancy determined according to Broders' method. In practically all cases (858 of the 887, or 97 per cent) the neoplasm was adenocarcinoma. In 22 cases or 2.5 per cent, the

¹⁰ Thompson G J, and Emmett J L. The Treatment of Carcinoma of the Prostate Gland by Transurethral Methods. *Urol & Cutan Rev* 39: 679-685 (Oct.) 1935.

lesion was squamous cell epithelioma and in 7 it was mixed and squamous cell carcinoma. It will be noted that in approximately 56 per cent of the cases the lesions were of grades 3 and 4.

Attention was called in a previous publication (Zide,¹¹ discussion by G. J. T.) to the necessity for

caution in examination of tissue removed by transurethral resection of the benign prostate when the operation is done in two stages. At the secondary operation some of the tissue removed will exhibit pronounced hyperplasia of the epithelium of the prostatic ducts. These are the cells which form the epithelial lining of the new prostatic urethra. An uninformed pathologist may easily mistake these cells for malignant ones and make a diagnosis of "cancer." This leads to at least two subsequent errors: either the use of roentgen therapy, which may cause great distress and needless expense, or formation of the false conclusion, years later, that "cure" of carcinoma of the prostate gland has been obtained. Furthermore, if the patient is informed that he has a "cancer" he will suffer unnecessary mental anguish.

POSTOPERATIVE COURSE

In the great majority of cases a one stage operation will restore normal urinary function. In recent years, in less than 4 per cent of cases, the patient has not voided freely and reoperation within a ten day period

has been done. The average stay in the hospital for members of the group as a whole was eight days, after which they were ambulatory and reported daily in the clinic, unless they resided within 50 miles of Rochester, in which case they returned home and reported to us at less frequent intervals, until they were finally dismissed from our care.

In the 887 cases there were ten deaths, or a mortality rate of 1 per cent. This includes all deaths, regardless of the cause.

The postoperative care of an aged patient who has carcinoma of the prostate gland is an art which will tax the ingenuity of any one. Perhaps more so than those who have benign conditions, they must be managed carefully lest bronchopneumonia, cardiac complications, renal insufficiency, intestinal disturbances due to fecal impaction, thrombophlebitis and a host of other afflictions impede and lengthen their convalescence. Very careful management of the indwelling catheter and judicious after-care to insure freedom in voiding are extremely important. Some of the principles of the care of these elderly patients have been described elsewhere.¹²

IRRADIATION

Of the 877 patients who survived operation, 206, or 23.5 per cent, were irradiated. With the exception of a few instances in which radon seeds were implanted into the prostatic capsule through the perineum, treatment was by roentgen rays, and a standard 200 kilovolt machine was used. In almost all cases between five and eight treatments, of fifteen to twenty minutes' duration

Status of traced patients who underwent transurethral resection as of Jan. 1 1942. The percentage and length of survival of those who had lesions classified according to one of the four grades of Broders also is shown.

each, were employed. Various fields were used, according to the best judgment of the specialist in roentgen therapy. I am not capable of presenting the details of this treatment.

In the period prior to 1937 70 patients received treatment. Sixty-nine of these were traced and of these 10, or 14.5 per cent, had lived five or more years.

SURVIVAL RATES

A composite chart has been prepared which shows the percentage of survivals according to years. It will be seen that as of Jan. 1, 1942 in the group of traced patients 75 per cent lived at least a year, 50 per cent lived at least two years and 30.2 per cent lived at least three years after operation. Other interesting figures pertaining to the various grades of neoplasms (Broders' method) may be noted by study of this chart.

It has seemed to me best to study particularly a group of 337 patients who were operated on prior to 1937. Three of these patients died in the hospital. In table 4 are presented the five year survival rates computed according to the grade of malignancy of the lesion. Of the 334 patients, 326 were traced and a total of 46

¹¹ Zide H. A. Changes in Prostatic Tissue After Operation. Proc. Staff Meet. Mayo Clin. 12: 769-772 (Dec. 8) 1937.

¹² Thompson G. J. The Prevention of Complications of Transurethral Prostatic Resection. Urol. & Cutan. Rev. 35: 847-851 (Dec.) 1934.

patients, or 14.1 per cent, were found to have lived five years or more after leaving the hospital. The survival rates computed according to the grade of malignancy of the tumor reveal that no patient who had a tumor of grade 4 survived operation for as long as five years.

A number of patients included in this group of 334 were still living (at the time of this report), some of them had survived for eight and even nine years postoperatively. In at least 2 cases it would seem that a cure had been established, for in 1 of them careful necropsy failed to reveal any evidence of a remaining carcinoma. In the other, subsequent transurethral resection of benign adenomatous tissue was done and there was no clinical or microscopic evidence of carcinoma. Reexamination of the tissue removed at the first operation confirmed the original diagnosis, evidently a small carcinomatous nodule within an adenoma had been removed at the first operation.

It should be emphasized that no claim to cure is made in any case, and that all the operations were done purely as palliative procedures. However, the fact that in 14.1 per cent of cases survival of five years was obtained is encouraging indeed. Certainly, among many of the patients who died prior to five years postoperatively the cause of death was in no way related to the prostatic cancer. They died, rather, of the other diseases which afflict men of this age group.

For some time I have thought that older men with stand carcinoma of the prostate gland better than younger men do. Yet study of this group of 334 patients, as shown in table 5, discloses little if any evidence to substantiate this clinical impression.

REOPERATION

It has been stated that the period of relief of urinary obstruction after transurethral resection of the malignant prostatic gland is short, in fact, so short as to make other types of operation preferable on this basis alone. Study of the records of patients who underwent operations prior to five years ago shows that as of the last report 66, or 20 per cent of the 334 patients, returned to the clinic for a subsequent operation. An additional 19 patients were operated on elsewhere after they had left the clinic. Thus, in the interval of at least five years which elapsed after operation 85 patients, or 25 per cent, have had a subsequent operation.

Only in extremely rare instances was an operation necessary within less than a year. The great majority of patients were able to void urine satisfactorily until death. Of the 46 patients who survived operation five years or more 16, or 35 per cent, required one operation or more subsequently. The interval between operations was as long as 6.5 years. Four of these 16 patients lived comfortably for more than five years between operations. This certainly suggests that carcinoma of the prostate gland is in some cases a slow growing tumor. Further, the study indicates that in a high percentage of cases complete freedom in the voiding of urine is provided by transurethral resection and that this freedom exists until the patient dies of metastasis or other unrelated disease. In my opinion transurethral resection during the past decade has been the beacon of hope for patients afflicted with prostatic carcinoma. By means of it rapid restoration of vesical function, at a minimal risk and with a short period of hospitalization, has been possible. If the operation is combined with Huggins' procedure of castration, the results in the future should be superior to those obtained in the

past decade. Certainly the outlook for any patient unfortunately afflicted with carcinoma of the prostate gland is brighter at present than it has been heretofore.

CONCLUSIONS

1 Carcinoma of the prostate gland is an insidious disease which usually does not cause symptoms until it is well advanced. It is difficult to detect in its early stages by any known clinical method.

2 In 95 per cent of patients the disease has spread beyond the confines of the prostate gland when they are first observed, in 5 per cent or less radical perineal prostatectomy may be justified as a method hopeful of cure in the strict sense of the word.

3 Transurethral resection is the most desirable operation for the relief of obstructive urinary symptoms caused by the disease. Entirely adequate relief for prolonged intervals follows if the operation is properly performed. Normal vesical function is achieved at minimal risk to life, and practically no risk of incontinence will result.

4 Transurethral resection of the obstructing tissue combined with bilateral orchietomy as suggested by Huggins, and the administration of diethylstilbestrol, seem to constitute the best method of treatment now available for patients who have retention of urine. Unless urinary obstruction exists, orchietomy and diethylstilbestrol therapy seem to constitute the treatment of choice.

PROSTATIC CARCINOMA TREATED BY ORCHIECTOMY

A PRELIMINARY REPORT BASED ON SEVENTY-FIVE
CASES OBSERVED FOR AT LEAST SIX MONTHS
FOLLOWING OPERATION

REED M. NESBIT, M.D.

AND

ROBERT H. CUMMINGS, M.D.

ANN ARBOR, MICH.

Our purpose in this report is to present data on 75 cases of prostatic carcinoma treated by orchietomy at the University Hospital and observed for periods of at least six months following that procedure. The diagnosis was confirmed by microscopic examination in 60 of the cases, in 15 there was no material removed for biopsy, the diagnosis being established on the basis of characteristic findings on rectal examination, with evidence of metastases by x-ray examination or by elevated serum phosphatase levels in all except three. Preoperative acid phosphatase determinations by the method of King and Armstrong were carried out in 28 of the cases. At the time this therapeutic project was begun, these determinations were not being made at the University Hospital Laboratory. Eleven cases (39 per cent) showed elevated serum acid phosphatase levels of 6 King-Armstrong units or higher. The preoperative determinations in these cases are given in the accompanying table.

There were 6 cases with x-ray evidence of metastases in which no elevation of acid phosphatase level was observed, 6 of the cases showing elevated serum acid phosphatase evidenced skeletal metastases.

Read in the Symposium on Treatment of Carcinoma of the Prostate Gland before the Section on Urology at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1942.

CLINICAL RESPONSE TO ORCHIECTOMY

Pain—The most spectacular feature of these cases is the early and satisfactory relief of pain, which occurs in from twenty-four to seventy-two hours in most instances in which relief is obtained. We have observed two or three exceptions to this general rule, however, in cases in which relief of pain came on very gradually after a period of several weeks. In 42 of the cases here reported pain of metastatic origin was complained of on admission. Five of the patients obtained no relief whatever following operation, while 27 obtained complete relief of pain and 10 obtained partial relief.

Weight—Eighteen patients complained of significant weight loss on admission to the hospital. Thirteen of these regained their weight losses. The operation on the remaining 5 was a failure, 2 are dead. Thirty-eight additional patients have had appreciable gain in weight since orchietomy, some gaining as high as 50 or 60 pounds (22 to 27 Kg.) during the minimum of six months under observation. The exact cause for this weight gain is difficult to determine. Undoubtedly several factors enter into the picture, including relief of pain, improvement in appetite, which is constant in all successful cases, and a sense of well being, which is generally noted.

Preoperative Determinations

	King Armstrong Units of Serum Acid Phosphatase
3 cases	6
2 cases	13
1 case	22
1 case	30
1 case	55
1 case	57
1 case	90
1 case	130

Urinary Obstruction—Fourteen patients complained of difficulty with voiding or complete retention of urine in whom orchietomy was performed and in whom no operation for the relief of prostatic obstruction was carried out. Five of these patients were placed on suprapubic drainage at the time of orchietomy. Three have regained the ability to urinate by urethra after shrinkage of the primary neoplasm. Two of these patients are still unable to urinate, although they have had a great reduction in the size of the prostatic tumor. Nine patients at the time of orchietomy complained of significant difficulty with urination. All these patients have experienced more normal urination since orchietomy.

Transverse Myelitis—Two patients were admitted to the hospital complaining of severe metastatic pain and transverse myelitis below the midthoracic level. Both had complete relief of pain and complete return of neuromuscular function following orchietomy.

One of these patients is of particular interest in two respects. He was given a therapeutic test of diethylstilbestrol therapy 1 mg. three times daily for a period of three months without relief of pain. The neurologic complications progressed during that time. At the time of orchietomy he had complete transverse myelitis and was receiving 3 grains (0.2 Gm.) of morphine daily

for pain. Following orchietomy he became free from pain within three days and at the end of one week he regained the ability to move his toes and within two weeks was able to move his legs normally. The second interesting and important feature was that after almost complete recovery from his symptoms and signs as well as reduction in the size of the primary tumor this patient had delayed return of symptoms after a period of four months' relief and is at the present time rapidly going down hill and is to be considered in the category of delayed failure.

Primary Lesion—Forty-one of the 75 cases have been examined rectally by two or more members of the urologic service at least six months after operation and are therefore available for objective evaluation.

Twenty-seven cases showed definite regression in the size of the prostate gland although still recognizable as carcinoma to palpation. The prostate in several has regressed in size and has become more soft in consistency than was noted on preoperative examination.

Eight cases have shown a regression in size so that the prostate is now atrophic, firm and smooth with no obvious infiltration either laterally or into the seminal vesicles.

The prostates in 6 cases have changed from a condition which was obviously malignant before operation to a consistency now unrecognizable as neoplastic by rectal examination. In these cases rectal examination discloses a prostate gland moderately enlarged, soft, noninfiltrated and objectively benign. Certain features of these 6 cases are of interest and will be enumerated as follows.

Two patients with massive carcinoma of the prostate with widespread metastases, put on suprapubic drainage, are now voiding satisfactorily with the prostate gland normal to palpation.

Two had advanced primary lesions with extensive infiltration locally and extensive metastatic lesions. One of these, besides having complete disappearance of all objective evidence of local malignancy, has had almost complete regression of extensive metastatic neoplasm as determined by x-ray examination.

One patient with an extensive local lesion without metastases but with a serum acid phosphatase level of 55 King-Armstrong units before operation has had a regression of the primary to a condition which is interpreted as being normal to rectal examination and has had a return of the elevated serum acid phosphatase level to 7.5 King-Armstrong units.

One patient with a large carcinoma with extensive infiltration rectally has returned to a normal state to rectal palpation, but x-ray evidence of metastases shows a constant progression of these lesions and the patient is at the present writing in a terminal state.

Skeletal Metastases—Positive x-ray evidence of skeletal metastases was found in 31 cases. In 12 of these an x-ray examination was made at least six months following orchietomy. Four show definite regression of the x-ray evidences of metastases, while 8 show an increase in the osseous changes noted in the x-ray film before gonadectomy.

SUMMARY OF RESULTS

Favorable Responses—In 48 cases pronounced clinical improvement has occurred. These patients have all shown regression of the primary neoplasm, have all

gained weight and all who had pain prior to orchiectomy are now free from it and all are voiding satisfactorily.

Seven additional patients have had complete relief of symptoms but there are no objective evidences of improvement either in the primary neoplasms or in the roentgenograms.

Unfavorable Responses—Five patients are dead. Four of these died of carcinoma, while 1 died of congestive heart failure and infection. This patient had a grade 2 neoplasm which was not extensive and should not be regarded primarily as a failure of the procedure.

Five of this group are alive. Five showed no favorable response at any time following operation have continued to pursue a downhill course and show advances in the primary lesion as well as the secondary lesions.

Ten of the patients whose treatment ended in failure showed an excellent clinical response and were symptom free for varying periods of time ranging from three to twenty-two months after orchiectomy before suffering return of symptoms. Five of these had a pronounced regression in size of the primary neoplasm which did not reverse at the time of decline. We have observed no significant improvement in the symptoms of any of these patients following the administration of diethylstilbestrol although all, whether failure was immediate or delayed, have had the administration of this medication.

In a recent communication summarizing postoperative results in 45 cases of prostatic cancer treated by orchiectomy, Huggins observed a considerable number of failures, some immediate and some delayed. In an effort to explain these failures on a basis of correlation with a microscopic finding in tissue removed from the primary neoplasm he classified the primary tumors according to pathologic appearance into two groups: adenocarcinoma and undifferentiated carcinoma. All the deaths from carcinomatosis and the patients, with no or slight improvement after orchiectomy, had undifferentiated carcinoma, while in the more satisfactory cases the pathologic appearance was adenocarcinoma. He concluded that a clinical course following orchiectomy could be related to the cellular pattern and stated that without exception the tumor was undifferentiated in all those patients who died from carcinoma, while it was adenocarcinoma in those patients whose course was satisfactory.

Pathologic material has been examined in 53 of our cases and has been classified on a pathologic basis into the following two types as grouped by Huggins: first, the well differentiated adenocarcinoma, and, second, those cases in which undifferentiated carcinoma is seen, in which acinus formation is not noted although the cells are recognizable as having prostatic epithelial origin and occur in medullary strands. The following observations in relation to response following orchiectomy were made in this group of cases. Adenocarcinoma was found in 31 cases, of which 27 have had favorable responses while 5 responses have been unfavorable. One patient died of sepsis and cardiac decompensation and therefore should not be critically considered as a failure. Two patients have given a completely unfavorable response since the time of

operation, and 2 have shown delayed failure, 1 having a return of symptoms after four months, the other at twenty-two months.

In the group of undifferentiated carcinomas there were 22 patients, with a favorable response in 16. Among the six failures, there are 2 who have died of carcinoma. 2 have had unfavorable response since orchiectomy and 2 have had delayed failure with a return of symptoms four months and eleven months after orchiectomy. It should be stated that many of the spectacular responses and some of the responses of longest duration thus far under observation have occurred in patients showing carcinomas of this type. Thus our observations in this series have not tended to substantiate those reported by Huggins in regard to correlation of neoplasm cell type.

Huggins found that severe hot flashes were seen in all of the cases favorably influenced by orchiectomy, but also were seen in certain of the unfavorable cases. Our observation in regard to hot flashes among the postorchiectomy cases are as follows: 1. There were 40 patients having hot flashes, of these, 30 were patients who had a favorable response while 10 were failures, 1 of whom is dead. 2. There were 32 patients having no hot flashes. Patients with favorable response having no hot flashes numbered 29, patients having no improvement 3. These observations suggest that hot flashes give little if any prognostic indication in this series of cases.

SUMMARY AND CONCLUSIONS

Seventy-five cases of prostatic cancer treated by orchiectomy and observed over periods of at least six months have been observed.

Elevation in the serum acid phosphatase level was observed in 39 per cent of the cases in which this determination was made.

Favorable response as determined by both subjective and objective criteria has been observed in 73 per cent of cases.

There have been 20 failures. Four patients have died of carcinoma and 1 from congestive failure and infection. Fifteen living patients are considered to be failures, 5 have shown no favorable response at any time following operation, while 10 are considered delayed failures, having enjoyed freedom from all subjective evidences of their disease for periods of three to twenty-two months before symptoms recurred after gonadectomy.

We have observed no satisfactory criteria for prognosticating the results of orchiectomy for carcinoma of the prostate.

The occurrence of 10 delayed failures in this series of cases with postoperative relapse at periods of from three to twenty-two months, offers disquieting implications regarding the ultimate outcome in any case.

Regardless of these implications or of the possibility of failure in some cases, it is evident that gonadectomy is a worthwhile procedure in advanced prostatic malignancy and should be recommended when the diagnosis is established.

We anticipate reporting again on this series of cases one year from now and it is hoped that other observers will continue their observations on similar series treated by other methods of endocrine control.

SERUM "ACID" PHOSPHATASE IN PATIENTS WITH CARCINOMA OF THE PROSTATE GLAND

PRESENT STATUS

ALEXANDER B. GUTMAN, M.D.

NEW YORK

While investigating the source of "acid" phosphatases in urine,¹ Kutscher and Wolbergs in 1935 discovered² that normal human prostate tissue is extremely rich in an "acid" phosphatase. This observation did not appear at first to have any special significance, since there are many phosphatases and they are widely distributed in animal and plant tissues. Further study of the enzyme, however, led to interesting developments among them a chemical method for the diagnosis of metastasizing prostate carcinoma, and the introduction by Huggins in 1941 of androgen control, an important new principle in the treatment of prostate carcinoma.

PROSTATIC "ACID" PHOSPHATASE AND PROSTATIC FUNCTION IN MAN

"Acid" phosphatase occurs in and is apparently elaborated by the acinar epithelium of the prostate gland, as Gomori³ recently demonstrated by a special histochemical technic. The concentration of the enzyme in adult human prostate tissue is extraordinarily high (500 to 2,500 units activity per gram of fresh tissue), many hundred times that of any phosphatase in kidney, liver, duodenal mucosa or bone⁴ tissues in which some role of the phosphatases in cellular activities is generally conceded.

The enzyme does not appear in appreciable amount in human or monkey prostate tissue until puberty. If puberty is produced precociously in immature rhesus monkeys by injection of testosterone propionate, maturation of the prostatic epithelium is accompanied by a rapid, several hundred-fold increase in "acid" phosphatase content to adult levels.⁵ High concentration of the enzyme seems to be an indication of physiologic maturity of the prostatic epithelium in man and the monkey.⁶

Prostatic "acid" phosphatase normally is excreted as a constituent of the prostatic fluid,¹ high concentrations being present in human seminal plasma ($3,700 \pm 500$ units to 700 ± 150 units per cubic centimeter in different individuals).⁷ Inseminated ejaculates constitute a medium suitable for effective action of "acid" phosphatase as they contain large amounts of the enzyme, a favorable milieu provided by the slightly acid pH of adult vaginal secretions, and potential phosphoric ester substrates.

The facts cited imply that prostatic "acid" phosphatase has some distinct physiologic function. The precise nature of this function is not known. It seems unlikely that the enzyme is active in the prostate gland (aside from contributing to the formation of prostatic corpora amylacea and calculi⁸), it acts probably only after it is secreted in the ejaculate. It further seems unlikely that the action of the enzyme in semen is directly on the sperm and therefore of very general significance, for "acid" phosphatase occurs in very high concentration only in the prostate gland of man and the monkey, whereas cat, rabbit, guinea pig and rat prostate tissue contain but traces⁹ and dog prostate tissue only moderate amounts.¹⁰ The enzyme perhaps participates in metabolic processes providing energy required by human sperm for prolonged motility in inseminated ejaculates.¹⁰ In man this energy is derived largely from the degradation of dextrose or glycogen¹¹ (in some other animals certain noncarbohydrate substances are utilized) and it is known that "acid" phosphatases elsewhere in the body catalyze dephosphorylation of phosphoric esters in the course of glycolysis (glycogenolysis). Further work along these lines is needed to throw light on that function of the prostate gland which in man appears to be mediated by the enzyme "acid" phosphatase.

"ACID" PHOSPHATASE ACTIVITY OF CARCINOMATOUS PROSTATIC TISSUE

Apart from occasional highly undifferentiated prostatic tumors which do not elaborate the enzyme,¹ carcinomatous prostatic tissue contains large amounts of "acid" phosphatase.¹² This holds not only for tumor tissue at the primary site but also for distant metastases. The presence of so much "acid" phosphatase in metastases secondary to prostate carcinoma may have some causal relation to the osteoplastic character of most such metastases to bone,¹³ but the mechanism of this relation is still obscure. The osteoplastic reaction is not due directly to the "acid" phosphatase of the metastasizing tumor tissue but to the increased "alkaline" phosphatase activity of the bone involved.

When carcinomatous prostate tissue metastasizes, invasion of lymph or blood channels is accompanied by escape of the prostatic secretion into the circulation, under these circumstances prostatic fluid becomes so to speak, an internal as well as an external secretion. Because of its high "acid" phosphatase content, the prostatic secretion present in blood can readily be detected by means of appropriate chemical methods for estimating the "acid" phosphatase activity of blood serum, which is increased by influx of the prostatic enzyme. This forms the theoretical basis for the now widely used determination of serum "acid" phosphatase activity in the differential diagnosis of metastasizing prostate carcinoma. The method is an interesting example of the possibility of establishing the primary

source of a disseminated carcinoma by chemical identification of its specific enzymic secretion in the blood stream

The high "acid" phosphatase content of most prostatic carcinomas indicates that these tumors are not composed of functionally embryonal cells (since immature prostatic tissue is virtually devoid of the enzyme) but represent a type of malignancy made up of physiologically mature epithelial tissue. Huggins and his associates¹⁴ were the first to grasp the therapeutic implications of this fact. They reasoned that, since normal adult prostatic epithelium can be made to atrophy by reducing the amount or neutralizing the effect of androgenic hormones, it might be possible to produce atrophy of malignant adult prostatic epithelium by castration or injection of estrogens. The validity of this deduction was demonstrated by a rapid pronounced fall in serum "acid" phosphatase¹⁴ and by striking symptomatic improvement in most patients with metastasizing prostatic carcinoma so treated.¹⁷ The

tion of breast carcinoma to gonadal hormones (thus far¹⁷ with no more than the limited therapeutic results obtained heretofore) and in applications to other tumors

"ACID" PHOSPHATASE ACTIVITY OF BLOOD SERUM

Normal human serum contains very small amounts of "acid" phosphatase,¹⁸ less than 25 units activity per hundred cubic centimeters of serum as determined by an adaptation¹⁹ of the King and Armstrong method for "alkaline" phosphatase. This normally occurring enzyme is not of prostatic origin; it is present in females as well as males, in children as well as adults, and its enzymic properties differ in significant though minor respects from those of prostatic "acid" phosphatase. Possible sources are liver, spleen, bone and kidney, all of which are known to elaborate "acid" phosphatases.

In 1938 the Gutmans²⁰ and Barringer and Woodward²¹ independently noted increased serum "acid" phosphatase levels in patients with metastasizing prostate

TABLE 1—Percentile Distribution of Serum "Acid" Phosphatase Values in Cases of Prostate Carcinoma With and Without Metastases, and in Other Conditions

		No of Cases Studied	Percentage of Cases with Levels of Serum Acid Phosphatase					
			Units per 100 Cc. of Serum					
			Less Than 3	3 to 4.9	5 to 9.9	10 to 100	100 to 1,000	More Than 1,000
Series of Sullivan and the Gutmans 1942	I Prostate carcinoma	200						
	a Bone metastases by x ray	10	10%	12%	20%	30%	9%	4%
	b No bone metastases by x ray	70	80%	11%				
	II Benign prostatic hypertrophy	70	100%					
	III Prostatitis	10	100%					
	IV Nonprostatic diseases	570	80%	70%	20%			
	V Normal	50	100%					
			Units per 100 Cc. of Serum					
			Less Than 4	4 to 6	6.1 to 10	10 to 100	100 to 1,000	More Than 1,000
Series of Herger and Sauer 1941	I Prostate carcinoma	147						
	a Bone metastases demonstrable by x ray or suspected	47	9%	4%	30%	30%	19%	2%
	b No x ray or clinical evidence of metastases	100	77%	22%*	1%			
	II Control patients	283	92.5%	70%				

Only 8 per cent control patients have serum acid phosphatase values between 4 and 6 units

amelioration of clinical symptoms produced by estrogens was noted independently by Herbst¹⁶. Final judgment of the value of treatment of metastatic prostate carcinoma by androgen control must await further experience, but it is already apparent that the clinical response in most patients is far more satisfactory than with any other form of therapy.

The effect of castration and estrogens in metastatic prostate carcinoma constitutes what is perhaps the most rigorous proof yet submitted that malignancy is not necessarily the result of an irreversible urge to grow intrinsic to the tumor cell but may be due in part to stimulation by extrinsic (in this instance endocrine) agents which are subject to some measure of therapeutic control. The results have renewed interest in the rela-

tion of breast carcinoma, the increase being due to the appearance in serum of an enzyme with properties corresponding to those of prostatic tissue "acid" phosphatase.²⁰ The applicability of this observation to diagnosis, prognosis and evaluation of treatment in prostate carcinoma has been the subject of many studies.²² Table 1 sum-

marizes the data obtained in the two most extensive of such investigations,²³ in which the same technique was employed. Elevated values, for the most part higher than encountered in any other disease, were obtained in about 85 per cent of a total of 177 cases of proved or suspected metastatic prostate carcinoma. About 90 per cent of patients with prostate carcinoma but without roentgenographic evidence of bone involvement gave values consistently less than 3 units (less than 4 units in the series of Herger and Sauer), as did all normal subjects all patients with prostatic disease other than carcinoma and more than 90 per cent of a total of 853 cases of nonprostatic disease. In general the determination has been reported by most investigators to be sufficiently consistent and specific to be useful, but some found the technical demands of the method too exacting and the results erratic and more confusing than helpful.

Apart from technical errors, the test may fail in patients with metastasizing prostate carcinoma because (1) the tumor tissue may elaborate so little "acid" phosphatase (owing either to pronounced anaplasia or to low endogenous androgen levels) that insignificant amounts of the enzyme are secreted into the circulating fluids (2) invasion of blood or lymph channels may be insufficient for escape of enough prostatic fluid into the blood, particularly in early cases or in cases in which the tumors produce little enzyme, (3) the "acid" phosphatase level may have been depressed by such treatment as injection of estrogens, castration, radical prostatectomy or intensive irradiation. The use of serum which has been allowed to stand too long results in low values, since the "acid" phosphatase level of shed blood slowly falls.

Falsely high serum "acid" phosphatase values occurring in patients with diseases other than metastatic prostate carcinoma most commonly result from the use of hemolyzed serums (Erythrocytes normally contain very large amounts of erythrocyte "acid" phosphatase, which on hemolysis diffuses into the plasma and raises the serum "acid" phosphatase level).²⁴ Slight to moderate increases in serum "acid" phosphatase, rarely over 5 or 6 units, not over 10 units, are encountered occasionally in nonhemolyzed serums of patients with nonprostatic disease, most frequently in advanced Paget's disease, carcinoma of the female breast with extensive bone metastases, hyperparathyroidism with pronounced skeletal involvement, and osteopetrosis. The slight rise in serum "acid" phosphatase in these conditions appears to be due largely to mobilization of the "acid" phosphatase of bone.²⁵

There is no general agreement at present as to the critical "acid" phosphatase level of the serum which may be accepted as diagnostic of prostate carcinoma with metastases. This is an empirical, in part quite arbitrary, figure subject to variation according to the methods and experience of different laboratories. Data obtained with the adapted King and Armstrong method as summarized in table 1 indicate that values below 3 units per hundred cubic centimeters represent negative, those over 10 units per hundred cubic centimeters definitely positive, results of the test. A very large proportion of proved cases of metastatic prostate carcinoma, however, have serum "acid" phosphatase levels

less than 10 units per hundred cubic centimeters. Results consistently between 5 or 6 units and 10 units may be regarded as indicative of metastasizing prostate carcinoma unless there is substantial clinical or x-ray evidence to the contrary. Values between 3 or 4 units and 5 or 6 units are borderline figures, though usually of diagnostic value. Their interpretation depends in part on the clinical roentgenographic and other chemical findings, in part on the trend in serum "acid" phosphatase levels observed in follow-up studies.

Sullivan¹⁴ recently introduced a provocative androgen test to facilitate interpretation of borderline values. This test is based on the observation¹⁴ that injection of androgen causes a rise in serum "acid" phosphatase in patients with prostate carcinoma that has already metastasized. Testosterone propionate is administered in daily doses of 25 mg. for five days, and it is then determined whether or not a significant rise above the initial serum "acid" phosphatase level has occurred.

As indicated in table 1, there is very wide dispersion of the serum "acid" phosphatase values encountered in different cases of metastatic prostate carcinoma from less than 4 units to more than 1 000 units per hundred cubic centimeters of serum. No correlation can be made out between the level of serum "acid" phosphatase and the extent, type or location of metastatic involvement, as far as this can be judged in roentgenograms. However, follow-up studies of any 1 patient with prostate carcinoma indicate that the development of metastases is accompanied by a rise in serum "acid" phosphatase above normal levels and that subsequent spread of secondary involvement is accompanied by further increases in serum "acid" phosphatase activity. In this sense the determination has prognostic significance. Herger and Sauer²⁶ found that the average period of survival of untreated patients with serum "acid" phosphatase values above 100 units per hundred cubic centimeters was significantly shorter than in cases with levels below that figure.

There is no correlation between serum "acid" and "alkaline" phosphatase levels in patients with prostate carcinoma except that both are normal before dissemination of the tumor and both are usually above the normal maximum after metastatic spread has occurred. The increase in serum "alkaline" phosphatase is of osseous origin²⁷ and reflects the extent and vigor of the osteoplastic reaction of bone at the site of skeletal metastases, if the liver also is involved, a further increase in serum "alkaline" phosphatase may result from obstruction to excretion of the enzyme in the bile. The rise in serum "alkaline" phosphatase is unspecific, being common to conditions characterized by wide spread accelerated osteoblastic activity or by obstruction of the biliary tract. The increase in serum "acid" phosphatase, on the other hand, is a more specific and constant manifestation of metastasizing prostate carcinoma. The "acid" phosphatase derives from the tumor tissue itself (though a small fraction in cases with extensive skeletal involvement may be mobilized bone "acid" phosphatase) and the level in serum is determined by the volume of neoplastic tissue and its capacity to form the enzyme, the extent of invasion of the tumor, the endogenous androgen level and similar

factors. The difference in origin of the two enzymes in serum is brought out with great clarity by their contrasting responses to castration.

CLINICAL APPLICATIONS OF THE SERUM "ACID" PHOSPHATASE DETERMINATION

The method is incapable of detecting prostate carcinoma which has not yet metastasized and is therefore of no value in the important problem of differentiating that condition from benign prostatic hypertrophy. Even in experienced hands the test fails in a significant though small proportion of patients with metastasizing prostate carcinoma. Moreover, there is enough overlapping of values in nonprostatic cases to give occasional falsely positive results. Despite these limitations, however, the determination has proved to be a useful adjunct to the usual urologic procedures, as indicated in the following summary of a more than four year period of clinical trial at the Squier Urological Clinic.¹¹

The most common function of the test in diagnosis was to corroborate by an independent, objective method the diagnosis of metastasizing prostate carcinoma made in patients with clinical indications of prostate carcinoma and roentgenographic evidence of metastases. The determination was often particularly helpful when interpretation of roentgenograms as regards the presence of metastases was inconclusive, at times the chemical determination made it possible to establish that metastatic spread had occurred months before this could be accomplished by use of x-rays. Differentiation of Paget's disease from osteoplastic metastases secondary to prostate carcinoma was facilitated by the test.²⁷ In patients known to have metastases to the bones, lungs, brain or elsewhere, with the origin of the primary tumor in doubt, it was possible by this method to establish whether the primary tumor was or was not carcinoma of the prostate gland, a matter now of more than academic interest.

The test proved useful also in determining the treatment of choice in patients known or suspected to have prostate carcinoma. A definitely and consistently increased serum "acid" phosphatase level was found to be a generally reliable contraindication to radical prostatectomy, even if evidence for metastases in roentgenograms was wanting or equivocal, the finding of normal levels encouraged radical surgery by reducing though not wholly excluding the possibility of extracapsular extension.

Effect of castration on serum "acid" phosphatase levels in 30 patients with metastasizing prostate carcinoma. The heavy line represents the average postoperative fall in serum acid phosphatase expressed in percentage of the preoperative level.

termination of serum "acid" phosphatase became an almost indispensable guide to the selection of patients for castration, the regulation of estrogen therapy and the critical evaluation of results with these several forms of treatment.

SERUM "ACID" AND "ALKALINE" PHOSPHATASE LEVELS IN PATIENTS WITH METASTASIZING PROSTATE CARCINOMA TREATED BY CASTRATION OR BY ESTROGENS

The determination of serum "acid" phosphatase activity offers a means for objective serial studies of the effect of gonadal and other hormones on patients with metastatic prostate carcinoma.¹⁴ It was this consideration that led Huggins to turn from a study of

TABLE 2—Effect of Castration on Serum "Acid" and "Alkaline" Phosphatases in Two Patients with Metastatic Prostate Carcinoma

	Case T B		Case L B

16 weeks	3.6	8.3	74.0	33.9

T B illustrates typical results when the clinical response proves to be very satisfactory. L B is illustrative of a refractory case with death occurring six months after castration.

castration in patients with benign prostatic hypertrophy (a problem which, largely for lack of suitable objective criteria, has been investigated for more than a half century with but indifferent success) to metastatic prostate carcinoma.

Huggins and Hodges¹⁴ found that in 7 of 8 cases of metastatic prostate carcinoma subjected to castration there was a sharp postoperative reduction in serum "acid" phosphatase to or toward the normal range, the serum "alkaline" phosphatase values rose following castration and then declined, more slowly than the serum "acid" phosphatase levels. In their case P R for example, the serum "acid" phosphatase fell from 26 to 5 units in seven days after castration, the "alkaline" phosphatase rose from 19 to a maximum of 41 units thirty-nine days after operation and was 20 units one hundred and four days after operation. In most instances these chemical changes were accompanied by pronounced, in some cases dramatic, clinical improvement.

Further data have been recorded by Sullivan and the Gutmans.¹² Castration in almost all of 31 cases of metastatic prostate carcinoma was followed by an early precipitous fall in serum "acid" phosphatase, often demonstrable after twenty-four hours, as shown in the chart. On the second postoperative day the mean decline was 55 per cent of the preoperative level, on the fourth day 64 per cent, the downward trend continuing until often temporarily arrested about the third week (occasionally in the second or fourth week) by a transient secondary rise. Thereafter the "acid" phosphatase usually showed a prolonged further decline until equilibrium was reached after several months. The final equilibrium level was 5 units per hundred cubic centimeters or less when the preoperative values

27 Gutman A B, Gutman Ethel B and Robinson J N. Determination of Serum Acid Phosphatase Activity in Differentiating Skeletal Metastases Secondary to Prostatic Carcinoma from Paget's Disease of Bone. *Am J Cancer* 38: 103 (Jan) 1940.

did not exceed 20 or 30 units but was apt to be considerably higher in patients with very pronounced preoperative elevations. The prognostic significance of such persistent postoperative increases in serum "acid" phosphatase (which Huggins and Hodges attribute to extragonadal androgens) is not yet clear.

For the first four days or week following castration, the serum "alkaline" phosphatase showed little change or fluctuated erratically, often falling below the initial value. After this latent period the values increased, usually during the second or third postoperative week, often to more than twice the preoperative level. A gradual decline then set in until, months after operation, equilibrium was reached at serum "alkaline" phosphatase levels usually nearer normal than those prior to castration.

While sufficient data are not yet at hand, there appears to be a significant parallelism between the response of the serum phosphatases and the clinical results of castration (table 2). Whereas clinical judgment of the success or failure of the operation may not be possible for weeks or months, however, it can generally be determined within forty-eight or seventy-two hours whether or not the chemical response will be satisfactory.

As regards the effect of estrogens on the serum phosphatases in patients with metastatic prostate carcinoma only meager data are available.²⁸ These make it clear, however, that estrogens in appropriate dosage generally cause a fall in serum "acid" phosphatase and a delayed rise in serum "alkaline" phosphatase. Regulation of dosage and objective appraisal of results in noncastrated or castrated subjects treated with estrogens are facilitated by (technically adequate) serial "acid" phosphatase determinations.

Irradiation of the testes has been advocated in cases of prostate carcinoma with metastases,²⁹ but very little is known, as yet, about the clinical and chemical results of treatment.³⁰

The gaps in this outline indicate how much remains to be learned about the effects of various methods of androgen control on serum "acid" and "alkaline" phosphatase levels in patients with metastatic prostate carcinoma. Such chemical studies may be expected to provide objective criteria in the solution of clinical problems of current interest. These include the relative value of the several methods of androgen control, their specific indications, the operative technique of choice in castration, the optimal dosage of estrogens and the management of patients who respond transiently or not at all to castration or to estrogens.

30 My own experience is limited to 2 patients who received sterilization courses of 1,200 roentgens. One H W had little relief of his presenting difficulties in urination and an unsatisfactory decline in serum acid phosphatase from 96 to 66 units per hundred cubic centimeters. Subsequent castration resulted in pronounced shrinkage of the enlarged prostate gland with striking symptomatic improvement and a persistent fall in serum acid phosphatase to 17 units per hundred cubic centimeters. The other patient J D showed only transient clinical benefit after irradiation and continued elevation of serum acid phosphatase (9 units per hundred cubic centimeters). Following subsequent administration of diethylstilbestrol he improved enough to resume light work. His serum acid phosphatase has been maintained at 22 units per hundred cubic centimeters.

BIOCHEMICAL THERAPEUSIS IN CARCINOMA OF THE PROSTATE GLAND

PRELIMINARY REPORT

WILLIAM P HERBST, M D

WASHINGTON, D C

The treatment of cancer of the prostate by means of alteration of the soil on which the cancer cells develop through the administration of diethylstilbestrol or estradiol dipropionate or by castration or both offers promise of being one of most helpful contributions in recent years toward the goal of biochemical control of malignant disease.

Contributions in the field of fundamental human biochemistry, including individual cell chemical composition and modification of vital processes in various types of cells through various physical and chemical application, are numerous.

Cholesterol is a key substance which is found in every cell and every fluid of the human body. On this

cholesterol base are built many steroid hormones which have profound influence on most genital organ cells but to a lesser degree on every cell.

In most of the group of chemical formulas appearing in figure 1, the identical base cholesterol may be noted. Despite the very slight difference in structure between estradiol and testosterone, these two substances have opposite effects on breast and prostatic epithelial cells.

Huggins¹ has demonstrated that (1) castration in man decreases the height of prostatic epithelial cells in

From the Department of Urology of Georgetown University Medical School Service of Gahlinger Municipal Hospital.

Read in the Symposium on Treatment of Carcinoma of the Prostate Gland before the Section on Urology at the Ninety Third Annual Session of the American Medical Association Atlantic City N J June 1st 1942.

Drs Dardimski Kelso and James Ash Colonel M C U S Army cooperated in the pathologic studies. Drs Charles D Lenhoff W B Lyles and Harold R Reed of Gallinger Municipal Hospital cooperated in the clinical observation and roentgen examination. The Ciba Company provided the estradiol dipropionate. The Research Department of the Winthrop Chemical Company provided the diethylstilbestrol. Dr Tomas Cajigas the U S Naval Hospital Laboratory and the National Cancer Research Institute assisted in the phosphatase studies.

normal prostatic tissue, (2) testosterone stimulates secretory activity of dogs' prostatic cells and diethylstilbestrol inhibits this activity, (3) acid phosphatase in cancer of the prostate with metastasis is elevated and (4) castration in man has so far produced spectacular response in the relief of pain and apparent stabilization or regression of local and metastatic lesions of the osseous system also elicit. He refers to the production of pituitary tumors by injecting large doses of estrogen in animals. Estrogen reduced androgen in 2 postcastration patients. He believed that continued androgen reduction is necessary to keep the activity of cancer cells controlled and that castration is the method of choice.

Kutscher and Wolbergs,³ Gutman, Sprout, Brunninger and Woodard⁴ and Herger and Sauer⁵ have also contributed brilliantly in the phosphatase research field.

CLINICAL OBSERVATIONS

In August 1940 a patient presented himself with a large malignant prostate and symptoms of nocturia (ten to twelve times) with very painful drop by drop micturition and in very poor physical condition. Having seen the exhibit of Drs. Huggins, Clark and Scott

Fig 2—Gradual clearing of osseous involvement over a period of 8 months

at the American Medical Association meeting in June 1940, in which the effects of diethylstilbestrol on a dog's hyperplastic prostate was demonstrated, it occurred to me that, if this substance had this effect on hyperplastic epithelium, it might have some influence on the cancer cells that come from these cells. I injected 1 mg of estradiol dipropionate into the deltoid and was surprised to learn forty-eight hours later that instead of getting up ten or twelve times the night before he had gotten up only five times, and, instead of painful dribbling dysuria, free painless voiding occurred. From that time until May 20, 1942 (twenty-two months) this patient has remained perfectly comfortable with the exception of occasional periodic increase in nocturia. Most of the time his nocturia amounts to three or four times and is always free and easy. The nocturia is dependent on the total amount of urine which he puts out and is variable. He has received

153 doses of 1 mg of estradiol dipropionate over a period of twenty-two months. The gland gradually has reduced in size from the size of a fist to a sausage-like mass the size of an index finger with a small knob at the top and at the bottom. His breasts have been enlarged and tender, and his penis and testicles have

Fig 3—Tissue from site of prostate

become reduced considerably in size. The phosphatase has remained below the upper level of normal. He is in excellent general health today.

Following this striking early experience and learning the observations of Dr. Huggins in June 1941, 20 more patients have been observed who have been treated with estradiol dipropionate or diethylstilbestrol, have been castrated, or both. Five patients received estradiol dipropionate, 8 received diethylstilbestrol, 8 were castrated, and of the 8 who were castrated 3 received diethylstilbestrol and 1 estradiol dipropionate before the castration, which leaves 4 patients who were treated by means of castration alone. Five of the cancers that were treated with estrogens alone were

Fig 4—Tissue of metastasis in adrenal

of the Bumpus⁶ type, that is, the very slow growing type, which seems to have a long expectancy. Of the Bumpus type group 3 were given diethylstilbestrol and 2 estradiol dipropionate and it was given symptomatically only, that is, for the relief of frequency or dysuria or interference with micturition or pain.

All of the castration patients experienced spectacular relief of pain from the local growth or metastasis. Five of these castrated patients had osseous metastasis and 2 had edema of the lower extremities. One of the castration patients was operated on when in extremely poor general condition and the operation was followed

Fig 5—Tissue of previously involved vertebrae but without demonstrable malignant cells

by a most spectacular convalescence. There was no acceleration or further development of the local growth or of metastasis in any of the castration patients.

Phosphatase studies on 11 patients followed the observation of Huggins⁷, Gutman and others. In all but 2 instances they were elevated in the presence of osseous metastasis or when the local growth was extensive. Two patients with extensive metastasis had no elevation.

DOSE

The dose to be employed has been 1 mg and not more than three times a week up until very recently. The selection of this dose was determined on with the feeling that it was a conservative dose and one which would not have too great a likelihood of too severely

Fig 6—Tissue from prostate which grew very rapidly during administration of diethylstilbestrol

upsetting the endocrine balance. In using endocrines it must be remembered that the dosage is not accompanied by an effect comparable to the amount given as with pharmacodynamic drugs. This dose of 3 mg

a week has been varied sometimes and a periodicity which seems particularly suited to the individual treated has been maintained. I have found that this periodicity sometimes varies in the same individual. I do not feel that large doses, that is 3 to 5 mg a day, are indicated in more than a small proportion of instances. Recently I have changed my mind with regard to using more than 1 mg at a dose owing to the fact that Dr Richard Gill of Wheeling, W. Va., told me of a patient who failed to respond to a dose of 1 mg three times a week but on being given 5 mg a day, was made entirely comfortable. Following this information from Dr Gill I had one experience in which increasing the dose from 1 mg of diethylstilbestrol three times a week to 3 mg a day materially relieved pain which previously did not respond. Other more recent experiences with larger dosage have been reported by Alyea,⁸ Chute⁹ and Wishard.¹⁰ Alyea has given 3 mg daily, as has Wishard. Chute gives 10 mg daily after orchiectomy with no untoward effects so far.

Nesbit¹⁰ has given 3 mg daily in treating benign hyperplasia and he has seen 3 patients die of cerebral

Fig 7—At right freedom from osseous involvement on Jan 10 1941. At left extensive involvement of spine and pelvis by May 5 1941.

hemorrhage of about 15 treated. Although Dr Nesbit does not feel that there was any relationship to therapy, I have the feeling that there may have been, through the production of a lessening of tensile strength of the cells in the blood vessel walls due to diethylstilbestrol.

Dr Wishard reports that he has used diethylstilbestrol on all patients suffering with cancer of the prostate who have been seen at the Indiana University Medical Center since July 11 of last year, whether they have primary carcinoma of the prostate or evidence of metastasis. "It has been well tolerated and no instance of complete failure to obtain some symptomatic relief has been noticed." Dr Wilbur Hames of Philadelphia told me of a patient whom he was treating with estradiol dipropionate who responded very nicely as far as his prostatic carcinoma was concerned but who developed a cancer of the brain which on exploration proved to be malignant but not prostatic in type.

¹⁰ Nesbit Reed. Personal communication to the author.

Metaplasia of the prostate, producing enlargement of the prostate, has been produced in man by Huggins through the administration of large doses of diethylstilbestrol and in various animals by Denning and others.

These data have changed my policy to one of giving 1 mg of estradiol dipropionate or diethylstilbestrol by hypodermic injection to start with. This dose is then decreased or increased as the symptomatic relief of the individual demands.

FURTHER OBSERVATIONS

Certain phenomena have been observed which are of interest. One patient treated with estradiol dipropionate had a purpuric syndrome with no explanation in the blood studies. The purpuric syndrome disappeared in forty-eight hours after the administration of 15 grams (1 Gm) of calcium gluconate after meals. After calcium gluconate was discontinued he developed a subconjunctival hemorrhage, which rapidly regressed on the resumption of calcium gluconate. Since that time this particular patient has been kept on a dose of 15 grams of calcium gluconate daily.

It has been of interest to note that the amount of urine excreted during the twenty-four hour period and

needed any further insulin since castration, which was done ten months ago (figs 6 and 7).

Figures 8 and 9 demonstrate a gynecomastia in a patient who had forty-five injections of 1 mg each of diethylstilbestrol. It is a typical female breast histologically.

Fig 9—Section through glandular portion. Note typical glandular structure of normal female breast. This specimen is the only one I know of which demonstrates the changes produced by diethylstilbestrol in the male breast.

Fig 8—Nipple of breast removed from this patient. Note well developed erectile muscle tissue typical of female breast.

particularly during the nocturnal twelve hours has been definitely reduced in many instances. This has also been observed in patients treated with estrogens for benign hyperplasia. This decrease in the amount of urine secreted partially explains the reduction in frequency among patients under this treatment. This phase of the problem should form the basis of an interesting research problem.

The prostatic mass regressed spectacularly in some patients, moderately in some, and not to any appreciable degree in others. In 1 patient on whom we had the opportunity of getting an autopsy following death by pneumonia eight months after castration and previous administration of diethylstilbestrol the prostatic mass was so small that it could hardly be recognized. There were malignant cells present microscopically in the tissue removed from the prostatic site (figs 2, 3, 4 and 5).

There was 1 instance in which carcinoma seemed to involve the osseous system like wildfire while the patient was being given 1 mg of diethylstilbestrol three times a week (figs 6 and 7).

In 1 patient who was on a regimen of 12 units of protamine zinc insulin a day to control diabetes, castration changed the diabetic situation so that he has not

Three specimens of tissue studied after castration and after diethylstilbestrol or estradiol failed to give any evidence, from a microscopic standpoint, that could be recognized as the effect of treatment.

Figure 10 is a photomicrograph taken from Dr. Huggins which demonstrated the amount of acid phosphatase in the carcinomatous cells.

Clute has found that the 17 ketosteroids did not indicate the degree of satisfactory response to treatment.

Lett of London in 1905 reviewed 99 cases of inoperable carcinoma of the breast in women who had

Fig 10—Acid phosphatase in rich concentration in carcinomatous acini in neoplasm of prostate. The demonstration of the enzyme in this tissue was made by the method of Gomori.

had oophorectomy at the suggestion of Beatson eight years previously. He failed to find more than 1 case which he considered permanently arrested in spite of the fact that as spectacular immediate response was witnessed as we are now witnessing in carcinoma of the prostate cases following castration.

SUMMARY

1 The basis on which the biochemical control of carcinoma of the prostate gland is based is the maintenance of a low androgen and acid phosphatase blood level

2 So far this has been accomplished as long as twenty-two months by estradiol dipropionate by me and as long as two and one half years or more by castration by Huggins

3 Chute advocates castration and large doses of diethylstilbestrol

4 Testosterone elevates blood phosphatase (Huggins) and therefore should be administered with caution in men. The dose of estrogens to be administered should not be more than required to maintain control of the malignant process, which is a variable and individual quantity

5 In view of the fact that microscopic study with ordinary staining methods has failed to demonstrate changes in the appearance of carcinoma cells, research in the field of biochemical staining methods similar to the Gomori method should be carried on

6 In some instances the malignant process may be accelerated rather than controlled by diethylstilbestrol

7 Should the prostatic cancer of patients who have been castrated cease to remain latent, as has occurred in carcinoma of the breast following bilateral oophorectomy it would seem likely that additional control may be maintained by giving estradiol dipropionate or diethylstilbestrol and possibly other biochemical agents not yet utilized or available

8 These relatively simple methods of biochemical control of prostatic cancer should have a wide field of application even though the control cannot be maintained indefinitely. The relief of pain alone more than justifies their use

9 Further coordinated collaboration between the clinician and the research laboratories, I hope, will ultimately solve the problem of continued biochemical tissue control

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS ALYEA AND HENDERSON, DR CLEVELY,
DR THOMPSON, DRS NESBIT AND CUMMINGS,
DR GUTMAN AND DR HERBST

DR ARBOR D MUNGER, Lincoln, Neb. We are in a new era in the therapeutics of prostatic carcinoma. The theorem of possible relationship of some factor in the testicle, probably androgenic, to carcinoma of the prostate was promulgated by me eight years ago before the Southwestern Branch of the American Urological Association and culminated in the report before the American Urological Association a year ago. This clinical observation was paralleled by a report of Dr Huggins, who embellished his clinical observation with careful scientific study of the relationship of serum phosphatase levels to carcinoma of the prostate, since which symposium there has been a rapid pursuit of this subject, establishing three schools, namely, the surgical castrationist or, as Dr Herbst has so aptly entitled his paper, the biochemical therapist, and the irradiationist. As between surgical castration and castration by the estrogens or castration by irradiation, equally parallel end results are being obtained. In surgical castration there can be no question that one removes the carcinogenic factor with the testicle. By so doing the gates are closed to proper search by the biochemist for that unknown factor in our biochemical economy which might answer the problem of endocrine relationship to carcinoma. Truly the relief by castration is frequently phenomenal, and the estrogen approach is probably fundamentally the most scientific approach to this subject. Following the paper which I presented on direct planned irradiation of the testicles,

I was rebuffed with statements that one cannot alter or destroy the interstitial cell of the testicle with x-rays. I am not in a position to present the histologic data accumulating on irradiated testicles but can say that, irrespective of whether or not the interstitial cells are thereby organically damaged, in 85 per cent of cases definite clinical improvement occurs parallel to the other types of castration and, I believe, more definitely so than with an estrogen alone. Prior to one year ago no phosphatase levels were studied, since which time all cases have been so studied. We see all sorts of vagaries in phosphatase level behavior before, during and after irradiation. There is no constant pattern which one can establish except that when the levels are above the accepted normal a decline is of good prognostic import. We are on the threshold of an epoch making revolution in our concept of the causes and treatment of carcinoma of the prostate.

DR H C BURRUS JR, Pasadena, Calif. With the increase in the incidence of the disease, a method for relieving much of the suffering it produces has been discovered. However, while urologists agree on the rapid relief of pain afforded there seems uncertainty as to the reason for the relief and disagreement as to the best method of obtaining it. Thus Dr Kearns, in agreement with the recent reports of Dr Dean from the Memorial Hospital, tells us that castration by upsetting the testicular pituitary-adrenal relationship does not reduce the androgen content of the blood as satisfactorily as estrogen administration and refuses to do castrations. While Dr Nesbit reports a case of transverse myelitis studied under equally careful circumstances in which no relief was obtained from diethylstilbestrol therapy over a three month period, during which time 1 mg of the drug was given three times a day yet following castration the patient was free from pain on the third day and at the end of a week was moving his toes. I believe that the proof of the greatest good done to the greatest number of patients with cancer of the prostate rests with the advocates of radical surgery, who as yet have not published lists or survivals in sufficient numbers to be convincing, if their records are compared with equal numbers of patients simply relieved of their obstructions. Now Dr Thompson comes forward with a report that it seems to me makes the position of the advocates of radical surgery still more untenable. He shows that by transurethral resection in a series of patients sufficiently large to be convincing statistically, with a mortality of only 1 per cent, 14 per cent live more than five years. Now that estrogens and castration are available to aid in the treatment of these men I predict that prolonged survivals will be so numerous as to make even the consideration of cure by radical surgery with the possibility of mortality and lifelong incontinence seem indeed fantastic. There can be no question about the prolongation of life following castration. When such outstanding investigators reach such diametrically opposite findings, it merely emphasizes how extensive is the field of biochemistry of the steroid hormones that still require investigation. As Herbst emphasizes, these steroid hormones probably affect more or less every cell in the body, and while we have learned an enormous amount concerning their behavior since the reports of Munger and Huggins, yet each case must be treated individually as to surgery or medication. No rule of thumb is applicable to all. I am already on record as being absolutely opposed to the attempted cure of cancer of the prostate by radical surgery.

DR JOHN H MORRISSEY, New York. This group of papers is distinguished by the absence of one devoted to the advocacy of perineal prostatectomy as a complete cure of prostatic cancer. When competent urologists with opportunities for clinical research find themselves in disagreement not alone on unimportant details but on fundamental principles as well, I wonder if we are not going overboard a little too early in the day as to final judgment on the values of these procedures. In none of the papers has there been any mention of handling the various symptoms of the patient with prostatic cancer and for which he consults the urologist. Instead, their frequency and dysuria diminishes overnight, they begin at once to eat better and gain weight, and all considerations as to secondary infection and its treatment are no longer necessary. The patient merely has to improve or get worse. Adequate attention should be directed to the problem of bladder drainage either by resection or by

cystotomy in all these cases. In a group of 18 cases in which operation was performed by me and my associates, we have had approximately 50 per cent unsatisfactory results. Curiously enough, these results show a definite relationship to the economic status of the patients. The worst results have all occurred in our municipal hospital cases in which after care, endocrine therapy—and in New York City it is impossible to prescribe any glandular preparations, even thyroid, for any patient without permission of the superintendent—is accomplished with increasing difficulty. Nursing problems due to the military situation have complicated matters still further. Handling this phase of the problem by early cystotomy in such cases in which it may be necessary is one solution, and Dr. Thompson has indicated his ideas along similar lines. When these patients are deprived of a glandular activity that contributes largely to their general well being, even though a neoplasia may at the same time be activated thereby, it is also important that continued attention be directed to the upper urinary tract and other foci of infection, caloric intake, vitamin therapy, and so on, all of which are likely to be below par rather than otherwise. Dr. Kearns is of the opinion that surgery is to be avoided and depends entirely on estradiol. I do not believe that all the surgical considerations of prostatic carcinoma, particularly cystotomy, from the standpoint of facilitating damage, can be thrown out of the window overnight.

DR. WALTER M. KEARNS, Milwaukee. Dr. Creely does well to call attention to the importance of early diagnosis. I have been especially interested in glandular therapy for some time and I used estrogens before Huggins announced his excellent results with castration. I continued to administer estrogens and have persisted with them ever since. My series now comprises 42 patients, about 70 per cent of whom were benefited in varying degrees. All of the results were obtained through the use of estrogens alone. First I used diethylstilbestrol. Later ethinylestradiol was used by mouth. Still later the subcutaneous implantation of alpha-estradiol was employed. The last named is the preferred method of estrogenic administration. It is especially applicable for patients who are unable to tolerate either diethylstilbestrol or ethinylestradiol by mouth. It may well be combined with the oral administration of diethylstilbestrol or ethinylestradiol. The one route of administration may be employed to augment the other according to clinical indications. In the *Journal of Urology* (47:587 [May] 1942) I describe a new trocar which the Beckton-Dickinson Company perfected for me for implantation of pellets of alpha-estradiol under the skin. I brought back into use in my practice the blood sedimentation test as a guide in estimating the status of carcinomatous patients. Hemorrhage and various things will influence the rate. The test may be carried out in its simplicity every time the patient comes to one's office if so desired. If you take up the use of the phosphatase test, take particular care about the technic. One must have a good electric photometer, a constant temperature bath and an expert technician. It requires very active work. I have drawn blood and divided it among five different laboratories, including Dr. Huggins's laboratory. Before our technic was standardized, diverse results with great variance between the different laboratories were obtained. Unless Gutman's technic, with one modification by Huggins, is followed very closely, the test is worthless. Pictures were taken at the onset of treatment. Six months later pronounced gain in weight was shown, with breast pigmentation and breast enlargement, which I consider a good criterion as to whether enough estrogen is being given. I start with 3 mg. a day of diethylstilbestrol or three tablets a day of estradiol and gradually diminish it and try to maintain a good effect on as small a dose as possible. Seven patients showed definite indications for surgery, but operation was postponed. Estrogens were administered from the very beginning, and the patients went on to improvement. With relief from symptoms, improvement in tests and shrinkage of the prostate gland they avoided surgery.

DR. CLYDE W. COLLINGS, New York. Most observers agree with Gershom Thompson that carcinoma of the prostate has been steadily developing in the patient's body for a considerable period before he seeks relief from obstructive symptoms. Like Bumpus, in the early days of transurethral surgery I advised

resection of this type of lesion as a palliative procedure. After operation the patient is happy if he can void freely, without discomfort. Furthermore, he would like to be relieved, as many agree, by a minor procedure, which gives maximum comfort with a minimal risk. As Thompson and the majority of the urologists of the present day feel, radical perineal prostatectomy is justified for only a small percentage of patients. When one weighs in the balance the results from total extirpation of the prostate, knowing this to be a very major operation, performed on an elderly patient, with a possible complication of incontinence of urine, I believe that the scales tip in favor of transurethral surgery. Surely the latter method of relief is a long step forward in comparison to the treatment of old, when a permanent suprapubic tube was used. True, there have been many more incontinence clamps sold since the advent of transurethral surgery. We at Bellevue Hospital in the remote past, and at the Los Angeles General Hospital in the recent past, have not had incontinence of urine as a complication, provided, of course, the surgeon stopped short of the verumontanum. We all have had the experience of trying to gouge out obstructing prostatic carcinoma through a suprapubic opening. It is comparable to the mountain laboring and finally bringing forth a mouse. The surgeon pushes tears and sweats, then brings forth a few nubbins. The late Dr. Edwin Beer, in a visit to the Urologic Clinic at New York University in the late 1920's, remarked "This cystoscopic picture, six months after transurethral surgery, shows a more efficient removal of the obstruction than we can accomplish by open prostatectomy." Our results parallel closely those obtained by Thompson. The mean age for our patients was 72 years. After operation they lived for an average of three and one half years.

DR. VINCENT VERMONTEN, New Haven, Conn. My remarks are based on observations in 58 cases of carcinoma of the prostate in which Dr. Neuwanger of Waterbury, Conn., and I have done bilateral orchiectomies. Six years ago we did a total radical prostatectomy on an old man for carcinoma. Six months ago he returned with extensive skeletal and pulmonary metastases but with no local recurrence. Before orchiectomy he was extremely dyspneic and practically moribund. Now he is once more able to be up and about and can do a normal day's work. Like Dr. Alyea's patients, his lungs are also once more completely free from metastases. This makes me wonder whether a radical prostatectomy for even an early lesion is really worth while. In 2 other cases in this series total incontinence of urine followed a bilateral orchiectomy. Fortunately they are among the few in our series in which a transurethral resection was not done. In regard to Dr. Creevy's remarks as to unsatisfactory prostatic biopsy by Ferguson's aspiration technic, might I suggest that he try the Silverman needle as recommended by Dr. Pierson of Salem, Mass. Using this needle I have been able to remove cylinders of prostatic tissue 1.5 cm. long and 1 mm. in diameter. It is easy to remove the tissue from any nodule or area that one chooses, and microscopically one gets a very good picture of the tissue removed. I have a patient who, having prostatic symptoms, was given 25 mg. of testosterone three times a week. This, over a period of three weeks, caused pronounced aggravation of his prostatic symptoms, the most annoying of which was prolonged, painful priapism. After bilateral orchiectomy his symptoms rapidly subsided. Now the prostatic symptoms have almost entirely disappeared but a mild transitory priapism still occurs when the bladder is very full. I feel that the danger of aggravating and stimulating the growth of a prostatic carcinoma, especially an occult lesion, must be borne in mind by those who choose to use testosterone for relieving prostatic symptoms.

DR. WILLIAM P. HERBST, Washington, D. C. This study has not simplified the problem of the handling of prostatic carcinomas. Unfortunately at this period there is no way to predict what the results are going to be. It seems that from the standpoint of the end results of castration the contribution by Lett on his follow-up on the oophorectomy in inoperable carcinoma of the breast in women will prove to be about as good a preview blue print of what is going to happen to our castration cases as one can think of. I am afraid that we shall have to look for all of the assistance that we have now plus additional help that I hope we are going to find through further

studies in the biochemical field along the nature possibly of further blood chemistry investigations, further study of tissue staining methods, such as the method of Gomori, whereby certain changes in the chemical constituents of certain cells may be recognized

DR C. D. CREEVY, Minneapolis The secretary of the section assigned this topic to me. I want to emphasize that I have advocated the radical operation only in the very earliest cases. During the period under discussion only ten radical perineal prostatectomies have been done at the University Hospital, and they were drawn from a group of some 500 carcinomas of the prostate. All of those who had any important obstruction to urination, except for the 10 included in the report, were treated by transurethral resection with or without irradiation. I should like to raise the question as to whether it is justifiable to attempt to cure any sort of cancer in any organ. I don't believe that the general surgeons, despite their low percentages of cures in carcinoma of the stomach or rectum, will concede that one ought to give up, and I still think that it is worth while to try for a cure in an appropriate case of early carcinoma of the prostate. I am inclined to hold to that point of view because we do not yet know for how long a period we can count on relief from castration or from the estrogens. If it is going to be just a flash in the pan, as was castration for inoperable carcinoma of the breast, then I don't think that the availability of the hormone preparations is a serious argument against radical perineal prostatectomy. We sometimes lose sight of the fact that an old man has as great a capacity for suffering as a younger man, and that he has a good deal less to lose by a radical operation of considerable magnitude than has a younger one.

HEREDITARY EPIDERMOLYSIS BULLOSA

CAPTAIN HARL D. MANSUR, JR.

Medical Corp. Army of the United States

Epidermolysis bullosa¹ is probably not a single disease but rather a group of closely related pathologic states differing in genetic and clinical forms. It is an uncommon, peculiar disorder of the skin occurring early in life and characterized by the development of vesicles and bullae following minor or insignificant trauma. It occurs in all races and the two sexes are about equally subject to it, with the male having a very slightly higher incidence. Fox^{1a} in 1879 first described the disease and Kobner¹¹ first used the name "epidermolysis bullosa" in 1886.

ETIOLOGY

The cause of the disease is not known. It probably is not a definite clinical entity. By some it is considered essentially an acantholysis at the junction of the epidermis and corium.

Referring to the hereditary form, Cockayne^{1a} divides the cases into several genetic groups, and he states that there is probably a group of closely related conditions included under this term. He suggests the possible close relation of this disease to "keratosis follicularis with vesiculation" and "familial benign chronic pemphigus." Since the bullae occur only on the extremities, some have likened it to sailor's or farmer's skin—just plain "senile atrophy." Some authors believe that the bullae are the result of sudden and excessive serous exudation in a person with an irritability of the

cutaneous vascular system, others insist that it is a trophic affair. Endocrine disturbances have been incriminated, and the allergist has likened the formation of the lesions to that of urticaria.

Cannon, Sanders and Rankin² made a complete bacteriologic study of the disease and found that the contents of the vesicles varied from clear fluid to frank pus and demonstrated *Streptococcus hemolyticus* of the group G strain present. They pointed out that this was not a contamination, since in 69 dermatologic cases picked at random from the Vanderbilt Clinic presenting twenty-eight different cutaneous diseases, no others showed a hemolytic streptococcus. The common organism consisted of *Staphylococcus albus* and *Staphylococcus aureus*, with an occasional *Streptococcus viridans*.

The histories of many cases indicate that consanguinity of parents may be a predisposing factor, also heredity plays a role in many instances. There are two forms—the simple, which is dominant, and the dystrophic, which may occur in both dominant and recessive forms.

The disease has been reported more frequently in Europe and is described under various names such as "acantholysis bullosa," "congenital bullous eruption," "congenital chronic pemphigus" and "pemphigus traumaticus."

SYMPTOMS

In the simple or benign form the lesions occur only on the skin, and the bullae usually heal without scars. The disease may be observed in early infancy, though it most frequently occurs during the first three decades of life and rarely after 50.

In the dystrophic type, bullae and sometimes hemorrhagic lesions occur on both the skin and the mucous membrane. On healing, the sites of former lesions are usually marked by bluish atrophic scars or, in the case of involvement of the mucous membrane, by leukoplakia. Oral lesions are said to occur in approximately 16 per cent of the cases of dystrophic type. The loss of nails and hair and the presence of epidermal cysts are not infrequent. Hyperhidrosis is common in either type.

DIAGNOSIS

The diagnosis is made by the presence of the bullae resulting from mechanical irritation. Nikolsky's³ sign, which is an absence of cohesion in the skin, wherein slight pressure easily removes the upper layers of the skin, is usually present. This sign is frequently present in the hereditary babe. Symptoms are exaggerated during the summer months, heat, hyperhidrosis and blisters are the common cycle of events. Some insist that leukopenia is the usual blood picture, while others have declared that leukocytosis is commonly present. The formation of bullae may be preceded by urticarial wheals. The blisters are monolocular and contain serum. After two to ten days they disappear without leaving an appreciable scar.

REPORT OF CASE

History—H. B., a white soldier aged 25, seen for the first time Sept. 19, 1941 shortly after his arrival at Sheppard Field, reported at the routine morning sick call and listed his complaint, "blisters of the hands and feet." Such a complaint was

not unusual from a recruit and nothing more than a superficial examination of the lesions was made and routine therapy given. He did relate at his first visit that all his folk had blisters which would not heal.

He stated that he had had these lesions as long as he could remember and that his mother told him that he had them in infancy. His past history was negative.

He made a return visit in one week, still with the same complaint, though his condition had become aggravated by his recruit training. Hyperhidrosis was strongly evident. We prescribed epsom salt soaks, hoping to cause some toughening of the epidermis. Later we tried salicylic acid, neither medication was of benefit. He returned to the dispensary every seven to ten days and improved sufficiently to start his technical training in the air mechanics school. He got along fairly well until it became necessary for him to walk about half a mile to the airport. His feet then became so painful that he had to stop school and be hospitalized.

His history further revealed that any pressure, even without friction, might cause these blisters to form. The lesions occur only on the dorsum and soles of the feet, and volar surfaces of the hands. A few have occurred on the legs where the supporter rubs. No lesions have existed elsewhere. In the formation of the lesions the skin becomes a deep red to scarlet, with a stinging, burning pain. This is followed by a clear, translucent, white plaque formation with a sensation of throb-

showed clear blisters, while other areas showed dense, firm, fibrous like bullae. Lesions were present in all stages.

Red blood cells numbered 4,675,000, white blood cells 6,950, with 70 per cent polymorphonuclear leukocytes. Urinalysis was negative. The sedimentation rate was 6 mm in one hour, the Kahn reaction was negative, cultures of the fluid

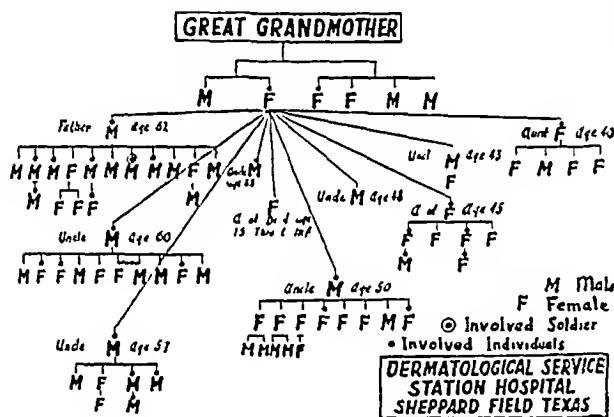

Fig 1—Graphic representation of the disease in five generations numbering 72 offspring

bing in the center. The latter symptom remains until the full bullae have formed. The throbbing can be lessened by elevation of the extremity, pressure over the lesions makes the pulsations worse. The stinging, burning like pain is severe enough to keep the patient awake if multiple lesions occur.

If the bullae are drained early only clear fluid is obtained, when they are not drained for five or six days a milky fluid is evident. If the bullae are not broken they will condense dry, peel off and heal, leaving no visible scars and a grossly normal skin.

There is no known consanguinity of the parents. His brothers and sisters were normal except those who had blisters like his. His father and many of his uncles and cousins had the condition also. They labored as coal miners when their feet permitted them to work.

The soldier stated that he had a 6 weeks old niece who had the disease manifested by formation of small bullae where the infant's toes rubbed when kicking the covers.

Figure 1 and the accompanying table show the occurrence of the condition graphically.

Physical Examination—The soldier was well developed and well nourished, was 67 inches (170 cm) tall and weighed 140 pounds (63.5 Kg). His blood pressure was 114 systolic and 65 diastolic and the Schneider index was +11. There were no physical abnormalities except for the lesions of the hands and feet. Some of the skin showed reddening, other parts

Fig 2—Early formation of bullae following the use of a broom for no longer than fifteen minutes

Fig 3—Bullae about 3 days old (at base of middle and ring fingers)

from the bullae showed gram-negative diplococci, biopsy reports stated that the specimen was compatible with the diagnosis of epidermolysis bullosa. Microscopic studies have shown a deficiency of or defects in the elastic tissue of the upper derma, the tissue adjacent to the bullae being perfectly normal. The subpapillary layer, and to a lesser extent the deeper portion, shows a rather decided basophilic degeneration. A moderate

amount of perivascular round cell infiltration is evident. Elastic fibers are much decreased in the papillary corium, especially beneath the bullae.

COMMENT

A few cases of "acquired epidermolysis bullosa"¹ have been reported since 1915. McLeod^{2a} reported that a retired army colonel at the age 50 suddenly had a

Fig. 4.—Formation of bullae on both heels and base of right small toe following about fifteen minutes of walking. Note old lesion of right small toe as evidenced by scaling.

bullous response to the slightest pressure on his hands, another case reported was that of a Polish woman aged 55 who insisted that her lesions had been present only six months and that none of her family or relatives were similarly affected. Such cases have been described as "epidermolysis bullosa tarda," that is, hereditary with tardive or delayed manifestations.

It is in these cases that the concept of a formal and causal factor is brought out. The causal factor, trauma, is of course so universal that one would expect the lesions to develop early in life. On the other hand, events somewhat analogous to those in cancer may take place, supplying the formal factor, and there is what is termed the acquired form, which comes late in life. Senile degeneration of supporting structures in the skin doubtless predisposes to the acquired form by rendering the skin more vulnerable to trauma.

There is not found in the case here reported any abnormality of the blood picture, although others have insisted on the presence of leukopenia and leukocytosis.

The patient had a Schneider index of +11, which would rule out cutaneous or vascular irritability as an etiologic factor.

TREATMENT

Most every salve, ointment, soap and powder of the dermatologist's armamentarium has been tried, with little or no good results. Cannon, Sanders and Rankin,² who proved the presence of hemolytic streptococcus in

the lesions, used sulfanilamide with complete absence of the organism afterward and definite improvement of all symptoms. Our cultures did not show any growth of hemolytic streptococci but instead showed gram-negative diplococci, which evidently was a contamination. We used 5 per cent sulfathiazole ointment applied to the lesions but could see no improvement or lessening of the formation of bullae.

Beinhauer⁴ of Pittsburgh treated 1 patient with a purified form of gonadotropic substance from the urine of pregnant women three times a week for a month. After the sixth injection the lesions cleared and ceased to reappear. Similar treatment of a mother and two sons with almost identical results was reported. We could not see the rationale of this therapy and therefore did not attempt to repeat it. No one else has reported the use of this principle in the treatment of this condition.

Kittredge⁵ reported the treatment of epidermolysis bullosa acquisita of twenty years' duration with iron cacodylate, which was effective at least temporarily in his 1 case.

We tried a preparation of histaminase, 2 tablets three times a day and at bedtime, for ten days on the theory

Occurrence of Hereditary Epidermolysis Bullosa

72 offspring	
0 members involved (17 males, 13 females)	
42 members not involved (20 males, 22 females)	
First generation	Great grandmother
Second generation	0 offspring 1 involved (2 females, 1 male) 3 not involved (1 female, 2 males)
Third generation	10 offspring 8 involved (2 female, 6 males) 2 not involved (1 female, 1 male)
Fourth generation	42 offspring 14 involved (7 females, 7 males) 28 not involved (16 females, 12 males)
Fifth generation	11 offspring 5 involved (2 females, 3 males) 6 not involved (4 females, 2 males)

that the condition might be a cutaneous sensitivity. The oral histaminase would in turn produce histamine, which should cause desensitization. Beneficial results were not observed.

Cold weather is of definite aid to these patients, and a soft leather, thick soled shoe is of great value. The only satisfactory treatment seems to be to take away the causal factor of trauma, which precipitates development of the bullae.

SUMMARY

The history of a 25 year old selectee having hereditary epidermolysis bullosa revealed that the family history showed thirty of seventy-two offspring in five generations had the disease. Seventeen of the members involved were males. Every one who had the condition was physically fit otherwise. The condition was proved to be hereditary, seems not to follow any mendelian ratio but shows dominant characteristics. The condition is evidently a congenital deficiency of the elastic tissue. No treatment that we have tried has given satisfactory results.

The soldier was given a certificate of disability for discharge, as being unfit for military duty.

Clinical Notes, Suggestions and New Instruments

A CASE OF LEAD ARSENATE POISONING
WITH RECOVERY

HERBERT H. KILGORE, M.D., AND PAUL S. RHOADS, M.D., CHICAGO

This is the report of a case of chronic lead arsenate poisoning occurring in a Michigan fruit farmer who had used this substance as a spray in orchards and vineyards over a period of thirty years. The paper is offered for publication because of the difficulty experienced in finding a clinical description of this combined chemical poisoning in standard textbooks on toxicology and medicine. The case reports of Stoddart, Riddell and Bulmer¹ and of Ayers² resemble ours in many respects. An excellent statistical report may be found in United States Public Health Service Bulletin number 267, published in 1941.³

In retrospect, the patient recalled that as long as five years before he had attacks of nausea and a quivering sensation of his muscles which kept him awake and restless at night but did not bother him while he was working. These symptoms were most noticeable the night following the use of the spray and decreased in intensity each night until the spray was again used, at which time there was an exacerbation of the symptoms. For two years he had had conjunctivitis, photophobia and blepharitis each time he used the spray. His family noticed that he tired more easily and was unable to do as much work as in former seasons.

Seven months prior to the time we saw him he noticed that his hands were cold and that numbness extended over the distal phalanges of his fingers. In one month's time the whole surface of his hands was numb and similar symptoms were starting in his feet. About this time he developed herpes zoster, and the eruption girdled his body in a 4 inch belt. He was confined to bed for three weeks. He complained that his feet were cold, and he received burns and blisters on his feet from the hot water bottles as a result of the lack of sensation. Vomiting became a prominent symptom and persisted for four weeks, this was accompanied by a considerable loss of weight. He noticed also that his epidermis scaled freely.

He was hospitalized at his local hospital four months after the onset of his illness, and at that time numbness had extended above his knees and up his arms, he had lost 40 pounds (18 Kg) and he could no longer walk. The loss of strength became more acute, so that he could no longer stand. He developed numbness of the tongue and lips, dysarthria and dysphagia and could not raise his head from the pillow. Numbness had extended to his waist.

Five months after the onset of his illness he began to improve when he was given liver injections, because pernicious anemia was suspected, but this improvement did not continue and he entered Wesley Memorial Hospital two months later, which was seven months after he first sought medical aid.

On admission the patient complained of weakness, loss of appetite, vomiting, numbness and tingling of his extremities, irritation and redness of his eyes and photophobia. The objective findings were ataxia with pronounced foot drop, obvious loss of weight, sallow complexion, anemia, conjunctivitis, blepharitis with lacrimation, and cheilosis. All teeth were absent. Basophilic stippling of the red cells could not be demonstrated. The outstanding findings were those related to peripheral polyneuritis with considerable motor and sensory loss. There was generalized weakness of both upper extremities, more especially in the hands, with atrophy of the first

dorsal interossei and the muscles of the thenar eminences. Flexion and extension of the feet and toes were feeble, and there was moderate weakness and atrophy of the muscles of the legs. The Achilles, knee and wrist jerks were absent. The triceps was diminished on the left but present on the right. The biceps reflexes were intact, as were the abdominals and cremasterics. Vibration sense was lost up to and including the knees and wrists. Joint sense of the thumbs, big toes and ankles was absent. Sensory loss to light touch was complete over the hands and feet, and there was diminished sensation to pain over the same areas. Increased myotatic irritability was generalized.

Laboratory examination revealed 3,850,000 red blood cells, 3,500 leukocytes and in the differential count 70 per cent of the cells were lymphocytes. The ascorbic acid level was 0.16 the icteric index 137, there was no free hydrochloric acid in the gastric contents.

Samples of urine, hair and nails were sent to the Cook County Coroner's Laboratory for chemical analysis and Dr. McNally reported that in 0.797 Gm of hair and nails there was 0.032 mg of arsenic trioxide, normally none should be found. Fifteen hundred cc of urine yielded 0.27 mg of arsenic trioxide, and there was 0.12 mg of lead per liter. One-hundredth mg of arsenic trioxide and 0.089 mg of lead are considered within the range of normal.

Lead and Arsenic Determination of Hair, Fingernails and Urine

-
- | | |
|--|--|
| 1 Before treatment | |
| 0.797 Gm of hair and fingernails yielded 0.032 mg of arsenic trioxide or 0.040 mg per gram | |
| After seven weeks of treatment | |
| 1.01 Gm of hair and fingernails yielded 0.06 mg of arsenic trioxide or 0.019 mg per gram | |
| Normally no arsenic trioxide should be found in 1.0 Gm of hair and nail | |
| 2 Before treatment | |
| 1,500 cc of urine yielded 0.27 mg of arsenic trioxide or 0.18 mg per liter | |
| Normal urine yield is 0.01 mg per liter | |
| 1,500 cc. of urine yielded 0.18 mg of lead per liter or 0.12 mg per liter | |
| Normal urine yields 0.089 mg of lead per liter | |
| No determinations on the urine were made after treatment | |
-

Treatment consisted of triweekly intravenous injections of 1 Gm of sodium thiosulfate and intensive vitamin therapy, especially with reference to the vitamin B group. This included brewers' yeast 1 drachm (4 Gm) with each meal, an ampule of a vitamin B preparation daily and 100 mg of thiamine hydrochloride on alternate days by intramuscular injection. Fifty mg of ascorbic acid and a capsule containing vitamin A, thiamine hydrochloride, riboflavin, ascorbic acid and vitamin D were given three times daily by mouth. He received 15 drops of diluted hydrochloric acid before each meal and a high vitamin diet, always in excess of 3,000 calories daily. Solution of liver extract in 1 cc doses twice a week intramuscularly and 3 grains (0.2 Gm) of a hematonic containing desiccated ferrous sulfate three times a day by mouth were given until the blood count became normal. The patient also received physical therapy in the form of heat and massage.

On this program there was a definite improvement in the neurologic findings, a gain of 25 pounds (11 Kg) and a return to normal in the blood picture, the red cell count being 5,120,000 at the time of discharge from the hospital. A second chemical analysis was done seven weeks after treatment was started. Three and seventy-one thousandths Gm of hair and nails yielded 0.06 mg of arsenic trioxide. It will be noticed that in this determination there was approximately four times the amount of hair and nails and only twice as much arsenic was found. The patient was released from the hospital to continue his convalescence at home.

Three weeks after returning to his home he wrote that he was walking about his farm as he desired and still gaining weight and strength.

Because of the improvement seen in this patient, the prognosis for a good recovery seems favorable.

FOLLICULAR LYMPHOBLASTOMA

WILLIAM E JAHSMAN M.D., DETROIT

Though probably first described by Becker¹ in 1901, it is only in more recent years that scattered reports of a new pathologic and clinical entity have appeared in the medical literature. Various titles have been given to this entity, among which are "giant follicular lymphadenopathy," "giant lymph follicle hyperplasia of the lymph nodes and spleen" and "follicular lymphoblastoma." Brill, Baehr and Rosenthal² were the first to call the disease to the attention of the medical profession in this country in 1925. They first thought that the condition was benign, but a follow-up of their cases revealed that most cases terminated with the clinical histologic picture of lymphosarcoma and hence they changed their original name "giant lymph follicle hyperplasia of the lymph nodes and spleen" to "malignant lymph follicle hyperplasia," and later, with Klem-

Section through axillary lymph gland of white woman aged 53 with follicular lymphoblastoma. The architecture of the gland is fairly well preserved. The follicles are considerably larger than usual. The germinal centers are pale and contain many mitotic figures. The sinusoidal spaces are quite well preserved but with some invasion by lymphocytes. Hematoxylin and eosin stain.

perer,³ to "follicular lymphoblastoma." These authors outlined the chief characteristics of the disease as follows:

- 1 Lymphadenopathy due to hyperplasia of the germinal centers of the lymph follicles
- 2 Splenomegaly frequent (60 per cent) and due chiefly to enormous enlargement of the malpighian bodies
- 3 Absence of abnormal cells in the blood
- 4 Absence of anemia and cachexia
- 5 Tendency toward development of serous effusions in pleural and peritoneal cavities
- 6 Absence of involvement of tonsils and the lymphatic apparatus of the gastrointestinal tract
- 7 Tendency to lymphatic infiltration in the lacrimal gland resulting in unilateral exophthalmos
- 8 Multicentric origin throughout the body in the lymph follicle, whereas lymphosarcoma arises monocentrically and spreads by lymphatic extension

1 Becker Ernest. Ein Beitrag zur Lehre von den Lymphomen. *Deutsche med Wchnschr* 27 726 (Oct 17) 1901.

2 Baehr George and Rosenthal Nathan. Malignant Lymph Follicle Hyperplasia of Spleen and Lymph Nodes. *Am J Path* 3 550 (Sept) 1927. Brill N E, Baehr George and Rosenthal Nathan. Generalized Giant Lymph Follicle Hyperplasia of Lymph Nodes and Spleen. *J A M A* 84 668 (Feb 28) 1925.

3 Baehr George, Klemperer Paul and Rosenthal Nathan. Follicular Lymphoblastoma (Giant Follicular Hyperplasia of the Lymph Nodes and Spleen). *Am J Path* 7 588 (Sept) 1931.

These authors stated that the entire process was a variety of lymphosarcoma and possibly might form a connecting link between systemic hyperplasia of the lymphatic tissue and lymphosarcomatosis.

Symmers⁴ reported interesting terminations of some of the 25 cases he reviewed, namely that:

- 1 In 7 cases polymorphous cell sarcoma had developed
- 2 In 7 others the condition was associated with Hodgkin's disease
- 3 In 4 others the condition was associated with lymphatic leukemia

In 1940 Baggenstoss and Heck⁵ reviewed 59 cases of the disease reported in the literature and 13 additional cases from the Mayo Clinic. The previous 59 cases included those of Fox and Roemmele,⁶ Kettle,⁷ deJong,⁸ Ikeda,⁹ Terplan,¹⁰ Ross,¹¹ McNee,¹² Cabot,¹³ Ewing and Fein¹⁴ and Symmers.⁴ Their observations were similar to those of Baehr, Rosenthal and Klemperer³ except that in some cases there was involvement of tonsils or retroperitoneal and mesenteric lymph glands. They also stressed the radiosensitivity of the lesions, although no permanent cures had been obtained.

To this total of 72 cases reported, Combes and Bluefarb¹⁵ recently added 15 presenting cutaneous manifestations but no splenomegaly. In the series there were 14 males and 1 female ranging in age from 15 years to 80 years—average age 55.6 years. Of the series of 72 patients previously reviewed, 47 were males and 25 females. The average age was 39.3 years, the range being 2 to 77 years. Only 9 patients were less than 30 years of age.

The prognosis for the disease is favorable because of the usually good response to roentgen therapy. But unfortunately after repeated irradiations the response is less spectacular, and finally this therapy is of little help. The average duration of life after the disease appears is four and one half years. But the condition may be mild, with exacerbations and remissions. Two patients are known to have been living seventeen years after symptoms first appeared.

To date, then, there are reported a total of 87 cases, so that the disease is still relatively uncommon. Because of this, with the possibility that it may be overlooked and the fact that it is an interesting condition, I wish to add 1 more case the first to be reported from the Henry Ford Hospital.

REPORT OF CASE

L. B., a white woman aged 53, American, was seen in October 1938 because of frequent attacks of infection of the upper respiratory tract with cough, purulent nasal discharge and thick mucoid sputum. The positive manifestations then were allergic rhinitis, nasal polyp, cloudy antrums and chronic asthmatic bronchitis. There were no enlarged lymph glands. The spleen was not palpable. Response to local nasal treatment, autogenous vaccine from sputum and simple medications was good through the winters of 1938-1939 and 1939-1940.

In April 1940 she was not quite as well generally. There was considerable itching of the skin. She attributed soreness

in the groins to coughing. But there were slightly enlarged glands in the inguinal regions, in the right axilla and in both cervical areas and a single larger gland in the left axilla. The spleen was 11 cm below the left costal margin in the mid-clavicular line. It was firm but not tender. There were no abnormalities of the chest. A blood count showed hemoglobin content 14 Gm, red blood cells 4,850,000, white blood cells 10,900 with 43 per cent polymorphonuclear leukocytes, 8 per cent eosinophils, 38 per cent small lymphocytes, 10 per cent large lymphocytes and 1 per cent monocytes.

By July 1940 itching of the skin had increased and there was more coughing. The appetite was poor with a consequent loss of 14 pounds (6.4 Kg). One month later her cough was more distressing and nonproductive and there was percussion evidence of widened mediastinal dullness in the first and second intercostal areas. This was thought to be due to enlarged mediastinal glands. Roentgenograms of the chest showed evidence of parenchymatous infiltration occupying the extreme left base and moderate accentuation of both hilar areas. The interpretation by the roentgenologist was possible mediastinal lymphoblastoma with lymphocytic infiltration of the left base. Follicular lymphoblastoma was now suspected and was confirmed by biopsy of an axillary node. The pathologic report was as follows:

Section through the lymph node revealed the architecture to be fairly well preserved. The capsule was comparatively thin but infiltrated in some areas with lymphocytes. The follicles were well preserved and appeared to be considerably larger than usual. Germinal centers were pale, and large numbers of mitotic figures were found within the germinal centers. The surrounding, more adult lymphocytes showed very few mitotic figures. The sinusoidal spaces were quite well preserved and there was little reticular hyperplasia. There was some invasion of the sinusoidal spaces by the lymphocytes, however. This lesion should be regarded as potentially malignant. The diagnosis was follicular lymphoblastoma.

A section from the lymph gland is shown.

There was good response to roentgen therapy to the chest, enlarged lymph glands and spleen. By September neither the spleen nor the lymph glands were palpable. The patient had gained 25 pounds (11 Kg), had no complaints and had resumed her usual household duties.

In April 1941, two enlarged cervical glands were again present. These caused no symptoms but were treated with roentgen rays and again promptly disappeared. Hemoglobin of the blood at this time was 14.0 Gm, and red blood cells numbered 4,650,000.

Enlargement of the spleen recurred in October 1941 and on November 24 measured 8 cm below the left costal margin. It was tender to palpation. There was increased itching of the skin. Small doses of roentgen rays over the spleen again caused complete disappearance of the enlargement by December 15.

On Feb 18, 1942 the hemoglobin content of the blood was 13.3 Gm and the red blood cells numbered 4,270,000. The patient was symptom free except for some itching of the skin and, for the first time, slight constipation. On June 15 the edge of the spleen was again just palpable at the costal margin and slightly tender. No enlarged lymph glands could be felt.

SUMMARY

The present case of follicular lymphoblastoma is the eighty-eighth to be reported in the literature. The patient is clinically quite well two years after symptoms began. She had no actual cutaneous lesions like those described by Combes and Bluefarb^{1,2} but did have annoying itching, as often occurs in Hodgkin's disease. She also had slight eosinophilia, as did 9 of Combes and Bluefarb's 15 patients. But more outstanding in this case were the characteristics of the disease emphasized in the 72 earliest cases reported, namely, insidious onset with regional or general lymphadenopathy, splenomegaly, the absence of anemia or abnormal cells in the blood, and the great radiosensitivity of the lesions.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AT THE REQUEST OF CENSORSHIP THE STATEMENTS ON TESTS AND STANDARDS ACTIONS, USES AND DOSAGE WHICH NORMALLY ACCOMPANY THE STATEMENT ON A PRODUCT NEWLY ACCEPTED FOR INCLUSION IN NEW AND NONOFFICIAL REMEDIES HAS BEEN WITHHELD FOR SULFA GUANIDINE UNTIL A FUTURE DATE. THEY WILL APPEAR IN THE COUNCIL PUBLICATION NEW AND NONOFFICIAL REMEDIES.

AUSTIN E SMITH M.D. Acting Secretary

DEXTROSE (See New and Nonofficial Remedies, 1942, p 418)

The following dosage forms have been accepted

CONTINENTAL HOSPITAL LABORATORIES, INC., CLEVELAND

Dextrose 5% W/V in Distilled Water 500 cc and 1,000 cc bottles. Each 100 cc contains 5 Gm of dextrose.

Dextrose 10% W/V in Distilled Water 500 cc and 1,000 cc bottles. Each 100 cc contains 10 Gm of dextrose.

Dextrose 20% W/V in Distilled Water 500 cc and 1,000 cc bottles. Each 100 cc contains 20 Gm of dextrose.

Dextrose 2½% W/V in Isotonic Solution of Sodium Chloride 500 cc and 1,000 cc bottles. Each 100 cc contains 25 Gm of dextrose and 0.9 Gm of sodium chloride-U S P.

Dextrose 5% W/V in Isotonic Solution of Sodium Chloride 500 cc and 1,000 cc bottles. Each 100 cc contains 5 Gm of dextrose and 0.9 Gm of sodium chloride-U S P.

Dextrose 10% W/V in Isotonic Solution of Sodium Chloride 500 cc and 1,000 cc bottles. Each 100 cc contains 10 Gm of dextrose and 0.9 Gm of sodium chloride-U S P.

Dextrose 5% W/V in Isotonic Solution of Three Chlorides 500 cc and 1,000 cc bottles. Each 100 cc contains 5 Gm of dextrose, 0.86 Gm of sodium chloride-U S P, 0.03 Gm of potassium chloride-N F and 0.033 Gm of calcium chloride-U S P.

SODIUM CITRATE (See New and Nonofficial Remedies, 1942, p 427)

The following dosage form has been accepted

CONTINENTAL HOSPITAL LABORATORIES, INC., CLEVELAND

Sodium Citrate 2½% W/V in Isotonic Solution of Sodium Chloride 70 cc in a 1 liter vacuum flask. A sterile 25 per cent solution of sodium citrate in isotonic solution of sodium chloride contained in a vacuum flask designed to permit aspiration of blood from the donor and subsequent administration of citrated whole blood to the recipient by gravity flow.

SULFAGUANIDINE—Sulfamylguanidine monohydrate—p-Aminobenzenesulfonfylguanidine monohydrate— $C_7H_{10}O_2N_4$, $S \cdot H_2O$ (M W 232.24)

E. R. SQUIBB & SONS, NEW YORK

Sulfaguanidine (Powder) 35 Gram envelope, 4 ounce and 1 pound bottles

Tablets Sulfaguanidine 0.5 Gm

LACTATE RINGER'S SOLUTION (See New and Nonofficial Remedies, 1942 p 430)

The following dosage form has been accepted

CONTINENTAL HOSPITAL LABORATORIES, INC., CLEVELAND

Lactate Ringer's Solution 500 cc and 1,000 cc bottles

ISOTONIC SOLUTION OF SODIUM CHLORIDE (See New and Nonofficial Remedies, 1942, p 425)

The following dosage form has been accepted

CONTINENTAL HOSPITAL LABORATORIES, INC., CLEVELAND

Isotonic Solution of Sodium Chloride 500 cc and 1,000 cc bottles

ISOTONIC SOLUTION OF THREE CHLORIDES (See New and Nonofficial Remedies, 1942, p 427)

The following dosage form has been accepted

CONTINENTAL HOSPITAL LABORATORIES, INC., CLEVELAND

Isotonic Solution of Three Chlorides 500 cc and 1,000 cc bottles. Each 100 cc contains 0.86 Gm of sodium chloride-U S P, 0.03 Gm of potassium chloride-N F and 0.033 Gm of calcium chloride-U S P.

SATURDAY, DECEMBER 5, 1942

FIFTH ANNUAL CONGRESS ON INDUSTRIAL HEALTH

The problems associated with the maintenance of industrial health continue to attract increasingly the attention of physicians, employers, workers and governmental agencies. Indeed, the hearings before the Pepper committee on education and labor served to focus the public eye on the situation. The program for the fifth Annual Congress on Industrial Health, on page 1145 of the Organization Section of this issue of *THE JOURNAL*, has been designed to illustrate how industrial health services can be extended and improved.

The demand for industrial health service has increased at a time when the facilities and personnel of medicine cannot assign the numbers of physicians and technicians necessary for ideal coverage. Intensified organization for the certification and training of physicians essential to industry becomes necessary, these plans will be discussed during the congress. The growing influence of labor in the industrial health program will be represented by a description of activities currently under way by employee-management production drive committees now organized in more than sixteen hundred plants at the request of the War Production Board.

A symposium on Infections in Industry will be conducted jointly with the Council on Pharmacy and Chemistry to include not only those of definite occupational origin but also others causing serious loss of time in industry, notably those affecting the upper respiratory system.

Another significant development in industrial practice is the changing nature of the work force, men are being replaced by women, older men, young workers and the handicapped. Each presents a new and different group of health problems.

Another session of the congress has been assigned to industrial medicine and the emergency. Here recent experience in functioning with less well trained help, the possibility of using technicians and aides to a

greater extent as replacements for more skilled people, more effective use of medical records as guideposts to needed preventive medicine and hygiene, and closer association between industrial medical facilities and those being set up for emergency medical care under the Office of Civilian Defense will be elucidated.

Innovations during this congress will be symposiums on Medical Relations in Workmen's Compensation, jointly presented with the Bureau of Legal Medicine and Legislation, and on Recent Developments in Rehabilitation, presented jointly with the Council on Physical Therapy.

On the last day a round table on Nutrition of Industrial Workers will be held in company with the Council on Foods and Nutrition and interested personnel from the National Research Council and the United States Public Health Service. Directly following this symposium a conference on industrial health to which the public will be invited will be held under the joint auspices of committees of the Chicago Medical Society and the Illinois Manufacturers' Association. Many other state and local organizations will collaborate.

An exhibit is planned which will demonstrate the industrial health services now available through agencies in organized medicine, public health and a few independent agencies. According to present plans, about thirty exhibits will be shown.

Once again this program reveals the desirability of focusing the attention of almost every phase of medical activity on the health problems of industry.

RECENT INVESTIGATIONS OF MARIHUANA

The practice of smoking marihuana has been credited with precipitating criminal acts, releasing inhibitions, lowering morals and leading eventually to mental deterioration. Hemp has been known as the source of fiber which goes into the making of rope and clothing and for its oil. The intoxicant of which it is the source has been called in different countries charas, ganja, hashish and other names. The Congress in 1934 passed the "marihuana bill," which provides regulations and penalties for use and distribution of the product as strict as those imposed for the use and sale of morphine.

The chemical, pharmacologic and clinical characteristics of the intoxicating principle of hemp have been the subject of a combined study by the University of Illinois, Cornell Medical College and Welfare Island Hospital. Results of these far reaching investigations, as reported by Professor Adams,¹ are of scientific and practical interest. The investigators at the University of Illinois isolated a substance which they term "cannabinol." At the same time, by developing a new procedure, they have isolated from this same oil Cahn's

¹ Adams, Roger. Marihuana (Harvey Lecture). Bull. New York Acad. Med. 18: 705 (Nov.) 1942.

cannabimol Cannabidiol, like cannabimol, proved to be physiologically inactive. However, the study of its structure and its reactions led to the determination of the structure of cannabimol and to the formation of tetrahydrocannabimols, products of high marijuana potency which are probably active principles in the red oil of hemp. Next, attention was directed to attempts to synthesize compounds of similar activity. A satisfactory procedure was devised for obtaining an isomer of the natural tetrahydrocannabimol. Loewe of the Department of Pharmacology of the Cornell Medical College applied his principle of "bioassay by approximation" to the ataxia test of Fiaenkel and thus established a reliable quantitative test for the potency of the substance.

Clinical studies of the effects of marijuana were conducted at the Welfare Island Hospital under the direction of Dr. Samuel Allentuck. A careful study was made on a group of 77 persons ranging in age from 21 to 45 years and from borderline to superior in intelligence, all voluntary recruits from one prison population. The maximum tolerated dose for each person was determined. At the same time, approximately the threshold at which psychotic changes first appeared was established. Tetrahydrocannabimol and the synthetic compounds dissolved in oil were administered by mouth in gelatin capsules and in some cases by intramuscular injection. Other clinical tests were made which involved intoxication from marijuana cigarettes. The observed physical effects one or more of which occur in each person are (a) elevation of the pulse rate, (b) elevation of the blood pressure, (c) injection of the conjunctival blood vessels, (d) dilatation of the pupils and sluggish reaction to light and accommodation, (e) circumoral tremors, tremulousness of the protruded tongue and the extremities, (f) dryness of the oral and pharyngeal membranes, (g) increased frequency, with decreased amplitude of thoracic respiratory movements, (h) ataxia and (i) hyperreflexia. The observed psychiatric effects are (a) apprehension and anxiety, (b) euphoria, (c) loquaciousness, (d) lowering of inhibitions, (e) hunger and thirst, (f) a feeling of being "high," (g) uncontrollable bursts of laughter or giggles and (h) drowsiness, languor, lassitude and a pleasant feeling of fatigue. Tolerance may be produced by repeated administration of subtoxic doses over a prolonged period of time. Marijuana is unlike opium derivatives in that it does not give rise to a biologic dependence accompanied by withdrawal symptoms. Neither does it establish a strong craving as exists in tobacco smoking or alcoholic indulgence. It is no more of an aphrodisiac than alcohol. A follow-up of the subjects has failed to establish the existence of any craving for the product.

The Welfare Island study of every phase of action of marijuana and the synthetic drugs did not reveal

evidence of any deleterious effects. It was felt, therefore, that some therapeutic use might be made of some of their properties. The drug, for example, could be used for persons in various stages of mental depression because of its euphoric effect. The invariable effect of these drugs in stimulating the appetite suggests that they might be applicable in psychoneuroses in which a lack of desire for food exists. The euphoria produced by marijuana is in many ways comparable to that achieved by the use of actual opium derivatives. This suggested the possibility of use in the treatment of addicts to opiate derivatives to eliminate or ameliorate the withdrawal symptoms commonly experienced during so-called cures. The preliminary clinical experiments by Dr. Allentuck with a group of drug addicts yielded encouraging results. A more exhaustive study of the possibilities of these drugs as a means of relieving withdrawal symptoms in narcotic addicts would seem to be justified.

COMPETITIVE BIDDING FOR INTERNS

Progress in medical education has been so rapid and so complex that one or more years of internship is uniformly considered essential to complete the preparation of the graduate in medicine for medical practice. The internships available for the continued education of medical graduates vary greatly in their quality. This, of course, makes necessary the comprehensive study of educational services in the hospitals of this country and the establishment of a list of approved internships by the Council on Medical Education and Hospitals of the American Medical Association. In the past fifteen years the number of available internships has advanced far beyond the annual needs of the graduating classes. This excess has partly been compensated for by the desire of some graduates to take more than one internship before beginning medical practice and by increase in the period of intern training in some hospitals.

As a war measure internship in hospitals of the United States does not now exceed one year, since medical school graduates are allowed only twelve months after graduation in which to complete their training before military service. Furthermore the number of residents has necessarily been reduced to a minimum—by at least one half. Finally, hospital staffs have also been greatly curtailed by entrance of physicians in the military services.

These developments have increased the demands for interns by hospitals and in some instances competitive bidding has extended to unwarranted salary levels. Frequently such salaries or honorariums are offered by hospitals whose educational program in itself appears to be inadequate to attract a sufficient number of interns. Competition for interns with the proffering of extraordinary salaries is not a new occurrence but has been

intensified by the present emergency. Heretofore medical school graduates have recognized the internship as an integral part of their educational program. They have tended to seek internship for the educational opportunities rather than for the financial returns. Fortunately the great majority of interns have always been interested primarily in educational merits and have looked askance at internships offering salaries beyond the ordinary allowance for incidental expenses.

Competitive bidding can be reduced to some extent if all hospitals will cooperate in maintaining a uniform and equitable distribution of interns in relation to clinical and educational needs. A hospital should not appoint an excessive number of interns to compensate for the loss of residents and other staff physicians. As a general rule the ratio of house officers to patients should not exceed one intern to six hundred annual admissions. Abuse of the use of interns by self-seeking administrators of hospitals might attract the attention of military authorities and lead indeed to an attack on the policy of deferment which now makes interns available.

Current Comment

COUNTY MEDICAL SOCIETIES URGED TO MEET REGULARLY

Significant in the address of Col. Fred Rankin, President of the American Medical Association, before the Annual Conference of Secretaries and Editors of State Medical Societies, was his recommendation for continuation of the meetings of smaller medical groups during the war. Already many national organizations of physicians and also some state societies have announced the abandonment of their annual sessions during 1943. The difficulties of transportation and the considerable demand on the time of the physician necessitated by travel to a distant point made such action necessary. However, such reasons do not prevail in relationship to the meetings of the county medical societies. The county medical societies are the organizations most concerned with the planning and support of the work of many agencies concerned in the war effort. To the county medical society come the requests of the Red Cross, the county and state health departments, the welfare agencies, the groups charged with the organized treatment of venereal disease, the care of the crippled and the tuberculous, and of other agencies which undertake important responsibilities during the emergency. To the county medical society also comes the need for recommendations to the Procurement and Assignment Service for Physicians, Dentists and Veterinarians, the organization of civilian defense, the blood donor program, and sometimes recommendations on the rationing of tires, gasoline, fuel and food. Moreover, physicians require during this time, perhaps more than at any other, the mental stimulation of inter-

change of medical information. Now is the time more than ever when local medical societies should be most active and supplement as far as possible the work of state and national associations.

NEW AND NONOFFICIAL REMEDIES, 1942

Since 1906 the Council on Pharmacy and Chemistry has issued annual revisions of New and Nonofficial Remedies. Each annual volume represents a milestone in the progress of the Council's work. The 1942 volume has just appeared. Those familiar with previous editions will note that a radical rearrangement of the contents and notable revision of the style have been made. This change should make the contents more accessible. Heretofore the classification of products has been basically that of chemical relationship, the new arrangement is based on therapeutic use, chemical classification being introduced by means of subheadings. In addition, the typographic style has been changed to give greater prominence to the products of individual manufacturers. Valuable features previously in use have not been sacrificed. The book still fulfils its function of establishing chemical standards for new and nonofficial preparations which the Council has found to be useful or to give adequate promise of usefulness in the treatment or prevention of disease. Its function as a guide to the most recent advances in therapeutics has been greatly enhanced. The Council has performed well its annual task of keeping the text abreast of the progress of medicine. The authoritative and compendious section of the sulfonamide derivatives is an example. So also is the chapter on vitamins and vitamin preparations for prophylactic and therapeutic use. Equally important though less extensive revisions have been made in such sections as those on aluminum compounds, dextrose, gonadotropic substances, liver and stomach preparations, ovaries, parathyroid, pituitary and testes. Among the newly accepted drugs are Acetyl-Beta-Methylocholine and the proprietary brand Mecholyl Chloride proposed for use by iontophoresis, orally and subcutaneously as a parasympathetic stimulant, Adrenal Cortex Extract for parenteral use in the treatment of Addison's disease or of adrenal insufficiency of other types as well as prophylactically in surgical procedures involving the adrenal cortex, Aluminum Hydroxide Gel with the proprietary brand Creamahn for oral use as an adjunct in the treatment of peptic (gastric and duodenal) ulcer, Normal Human Serum, and Normal Human Plasma. Others worthy of mention are Cyclopropane, another general anesthetic, now included in the U. S. P., Anylicaine Hydrochloride, another proprietary local anesthetic, and Pernoston Sodium, the sodium salt of the previously accepted proprietary barbitol derivative Pernoston. This volume should be available to all physicians, pharmacists and others interested professionally or commercially in drug therapy. One cannot commend too highly the unselfish and untiring efforts of the Council on Pharmacy and Chemistry in the preparation of this invaluable contribution to rational therapeutics.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

SURGERY IN RUSSIA

ACADEMICIAN BURDENKO AND HIS SCHOOL

DR ALEXANDER LEPUKALN
Moscow

NOTE—The following paper was radioed to THE JOURNAL from Moscow. The article is printed here primarily because of the unusual circumstances associated with it.—Ed

This article contains a concise review of work done by Academician Burdenko and his school. Its purpose is to inform our American friends about problems pursued by one of the leading schools of Russian surgeons.

Academician Burdenko was born in 1878 in a family of poor employees. His grandfather was said to have been a serf. In 1906 he graduated from Derpt University. Four years later, in 1910, he received his professorship, being only 32 years old, one of the youngest professors at that time. This was the chair formerly occupied by the conspicuous Russian surgeon Nikolai Ivanovich Pirogov. Appointment of a 32 year old professor to one of the most ancient universities was an unusual event which could have been explained only by the extraordinary ability of the candidate.

The first steps of this beginning in surgery coincided with the period of rapid development of this branch of medicine. It will, however, be noted that clinical thought of that time was confined to anatomy and pathologic anatomy; it dwelt mainly on morphology. Hardly any one of the surgeons was at that time interested in introducing into scientific clinical work achievements of experimental medicine and physiology. Nikolai Burdenko was one of the pioneers among clinical surgeons who endeavored to introduce into clinical work the elements of experimental medicine such as physiology, bacteriology and later on, with progress of chemobiologic sciences, of these disciplines as well. This is one of his greatest merits.

Methods of physiologic experimentation used by Burdenko were studied in the laboratory of his great compatriot Ivan Petrovich Pavlov as well as abroad. His interest in the nervous system led him to the study of anatomy and histology of this system. His first publications deal with physiology of the liver and pancreas. In his thesis "Contributions to Consequences of Ligating Venae Portae" (1909) he was one of the first students to experiment on exclusion of the portal circulation. At about the same time his publication appeared on plastics of radicles of the spinal cord. The purpose of this work was to form two collateral bundles of neighboring pairs of radicles at the level of a defect of the spinal cord. One of the first publications on heart surgery also belongs to this author.

In 1914-1917 his academic activity was interrupted by the first world war, in which he participated as consultant surgeon at the front. There he worked in

dressings detachments in field hospitals and carried on great organizational work. Along with the problem of abdominal surgery and of cerebral wounds he paid much attention to anaerobic infection. By that time he had also developed his method of treatment of gas poisoning at the front. At the end of the war Burdenko occupied the position of Chief Army Medical Inspector of the army. It may be mentioned in passing that Burdenko is a man of great personal courage and was awarded the soldiers' George Cross during the Russian Japanese War. To this he has since added three Soviet orders.

After the war of 1914-1918 surgery was occupied with postwar traumas, which led to problems of trophics. In this way the neurosurgical trend of study became separated as an independent branch of medicine. So-called late complications of lesions of the central and peripheral nervous system have also contributed to the development of neurosurgery as an independent branch of surgery.

Active part in the solution of these problems is played by Burdenko and his school. Numerous papers have been published both in this country and abroad by Burdenko and his associates on conductivity of pain and on sensitivity on surgery of tumors of the third and fourth ventricles of the brain.

In revising current concepts on the pathogenesis of stomach ulcers, surgical thought comes again to the problem of trophics and the significance of subcortical centers and of other components of the nervous system in the initiation of ulcerative process in the gastrointestinal tract. Experimental clinical work on this subject by Burdenko and his associates have been cited in particular by the American neurosurgeon Harvey Cushing. The doctrine of trophics has raised the problem of oncology of the central nervous system, which has also contributed to the development of neurosurgery. In the Soviet Union Burdenko is the acknowledged leader of this domain of surgery.

In 1929 he organized his clinic and two years later the Neurosurgical Institute was founded on this basis, well equipped with all modern technic. For the first time cooperative research in neurosurgical problems was adopted. In addition to clinical laboratories, others were organized, including biochemical, pathoanatomic and other laboratories headed by prominent specialists not only in surgery and neuropathology but also in histology, physiology, biochemistry and ophthalmology. Owing to this method of research, Burdenko was in a position to make important contributions to neurosurgery.

Besides the Neurosurgical Institute, Burdenko is also head of the chair of surgery at the Moscow Medical Institute. Here also the same principle of cooperative research, so characteristic of his school, is being followed. He cooperates with bacteriologists, biochemists and physiologists in his studies on disinfection (bio-

logic, chemical and mechanical) of infected wounds. Valuable suggestions as to the treatment of these wounds have resulted from his cooperation. Problems of blood transfusion have also been taken up by this school, in particular of immunized blood.

Burdenko's clinic was the first among Moscow clinics to take up in 1932 problems relating to active surgery and resection of the lungs. Here also studies in endocrinologic surgery and in hemophilia as well as in other branches of surgery have been inaugurated.

Mention has already been made of the problems directly concerning military field surgery as developed by the school of Burdenko (problems of blood transfusion, disinfection of wounds, traumatology). In this respect particular attention is due to studies in traumatic shock. Years devoted to this problem have clarified and improved current theories of the etio-pathogenesis of traumatic shock. One of the latest studies of Burdenko in this direction deals with Sharding's enzyme and the nature of the final receptor of molecular oxygen brought by the blood.

We do not dwell here on results obtained by Burdenko and his school in developing the theoretical basis of military field surgery. It will only be mentioned that within recent times much work has been done on this problem, the results of which may be found

in articles and instructions which are successfully applied for treatment of wounded defenders of our fatherland.

Such is a brief outline of the work done by Academician Burdenko. This trend of surgery may be termed biologic. This implies methodologic presumptions of experimental clinical character. Biologic approach to morbid process in the organism as a whole inevitably leads to cooperative methods of work.

I did not mention here the activity of Academician Burdenko as an organizer and outstanding social worker. It need only be recalled that he is a member of the Supreme Council of the Union of Socialist Soviet Republics, chief surgeon of the Red Army, president of the Association of Surgeons, one of the editors of the surgical journals and president of the Scientific Medical Council of the Commissariat of Public Health and of numerous other committees.

Surgical congresses are the supreme form of organization of surgical thought in our country. Over a number of years Burdenko has been elected president of these congresses. The Scientific Medical Council, headed by Burdenko, controls scientific research work in this country and charges personnel of many surgical clinics and hospitals of Moscow at other cities with a number of scientific, practical problems.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

APPEALS PROCEDURE

The directing board of the Procurement and Assignment Service has issued the following appeals procedure for individual physicians, dentists and veterinarians, and for employers thereof, to all state chairmen.

The responsibility for the initial decision as to whether an individual physician, dentist or veterinarian is to be considered essential in his present situation or available for service else where rests with the respective state committees. The local, county or district committees may serve in an advisory capacity to the state committee, but the authority to make decisions rests with the state committees.

If an individual physician, dentist or veterinarian or the institution employing him does not agree with the decision of the state chairman as to his availability for service elsewhere, the individual or his employing agency may request a reconsideration of the decision by the state committee. If the original

opinion is upheld by this committee appeal may be made to the corps area chairman and his committee. In this event the corps area chairman should request all information available from both the state committee and the person himself, and the corps area committee should appraise the situation and render a written decision to both the state chairman and the individual concerned.

If the decision of the state committee is still sustained by the corps area committee, the individual concerned or his employer has the further privilege of submitting his case to the central office of the Procurement and Assignment Service. When this is done the central office will assemble all pertinent information from the individual, his employer and the state and corps area committees concerned and present this for action to the directing board or to a special committee of the board in case a decision is necessary before the next board meeting. In such circumstances this committee shall report the case and its decision to the board at its next meeting.

ARMY

CITED FOR GALLANTRY IN ACTION

Dr Charles A. Baumhauer, Whistler, Ala., has been awarded by General MacArthur's headquarters a silver star for gallantry in action. According to the *Journal of the Medical Association of the State of Alabama*, Dr. Baumhauer exposed himself to enemy fire to assist wounded comrades during an air raid on Port Moresby on April 26, and the citation read "He did a great deal to relieve the pain and suffering of wounded men and helped establish a feeling of safety and security among the personnel, who had been through a harrowing experience." Dr. Baumhauer graduated from Tulane University School of Medicine in 1938.

AIR AMBULANCE SERVICE

Speaking on the radio from Cairo, Egypt, Denis Johnstone gave an account of the air ferry ambulance service of the Royal Air Force, which he said was saving many lives. This is a shuttle service of transport and ambulance planes, which during the recent campaign flew army casualties and enemy wounded

from the forward areas back to the base hospitals. They have been especially useful in cases requiring blood transfusion. These air craft carrying the wounded are unarmed and uncorted and fly by day and by night, sometimes landing along a flare path at the end of their journey like bombers coming in from a night operation. It thus becomes possible for the seriously wounded to be transported hundreds of miles within a short time to adequate medical aid and hospital facilities.

ARMY PROMOTIONS

Lieut. Col. S. C. Schwartz in command of the Station Hospital at Fort Thomas, Indiana and George E. Armstrong, assistant commandant of the Medical Replacement Training Center Officer Candidate School, Camp Berkeley, Texas, have been promoted to colonel, and Major J. H. Carson and Capt. L. E. Burnelle and Rosendo Forteza, all on duty at Fort Thomas, Indiana, have been promoted to lieutenant colonel and major, respectively.

Lieut Comdr Arthur P. Black, U. S. Naval Medical Corps (R), has received the Sir Henry Wellcome award of 1942 of the Association of Military Surgeons of the United States. The ten manuscripts submitted in the competition were on the subject Measures of Preventive Medicine Recommended by the Federal Medical Services to Insure the Maximum Improvement of the Selectee of 1961 over Him of 1941. Commander Black graduated from Johns Hopkins University School of Medicine in 1926 and was the third successive naval officer to win this annual award. The second award in the competition went to

Lieut. Col. Henry Pleasants Jr., West Chester, Pa., U. S. Medical Reserve Corps. Lieutenant Commander Black is at present on duty at the Naval Air Station at Kingsville, Texas.

Another course of instruction for aviation physiologists began on November 9 at the School of Aviation Medicine, Randolph Field, Texas. Among others, the following doctors of medicine were members of the class:

1st Lieut. William H. Bachrach	1st Lieut. William S. Maurer
1st Lieut. Joseph H. Harkenschel Jr.	Capt. Ward A. Peterson
Capt. Richard M. Leick	1st Lieut. Irwin C. Winter

The President of the United States has renominated Rear Admiral Ross T. McIntire to be chief of the Bureau of Medicine and Surgery of the U. S. Navy. Admiral McIntire graduated from the Willamette University Medical Department, Salem, Oregon, in 1912, and has been a member of the Navy Medical Corps since 1917. He was first appointed Surgeon General of the Navy in 1938. According to the *Army and Navy Journal*, Admiral McIntire declared a few days ago, in a radio address in answer to criticism and newspaper items concerning the large number of doctors being ordered to military service, "When the Marines go into battle, our people go with them, so when I hear statements made that perhaps we have too many doctors to care for our fighting men I want you to know that this is not so. We are only adequately furnishing medical personnel so that the lives of the wounded men who may be your sons can be saved. I can assure you that there will be no waste of medical personnel."

Portraits in oil were recently presented to the Surgeon General of the Navy for placing in the new Naval Medical Center at Bethesda, Md. The portraits were of William P. C. Barton, first chief of the Bureau of Medicine and Surgery of the Navy (1786-1856), Jonathan M. Goltz, chief of the Bureau of Medicine and Surgery (1810-1877), and Elisha Kent Kane, medical officer of the U. S. Navy (1820-1857). The portraits were presented by Mr. J. J. Brodbeck of the Ciba Pharmaceutical Products, Inc., and were accepted by Rear Admiral

Charles M. Oman, commanding officer of the Naval Medical Center.

On the same day the Ciba Pharmaceutical Products, Inc., presented paintings to the Surgeon General of the Army at the Army Medical Library of Charles S. Tripler, brigadier general, Army Medical Corps (1806-1866), for whom the Army General Hospital at Honolulu is named, Jonathan Letterman, surgeon major, Army Medical Corps (1824-1872), for whom the Army General Hospital at San Francisco is named, and Bernard J. D. Irwin, brigadier general of the Army Medical Corps (1830-1917). The speech of acceptance for the army was made by Col. Harold W. Jones, librarian of the Army Medical Library.

The Naval Medical Center at Bethesda, Md., has taken the first Women's Reserve Officers into its staff. Lieut. (j. g.) Cornelia Gaskill is enrolled in an indoctrination course at the Naval Medical Center preliminary to duty as a medical officer with the Women's Reserve. Lieutenant Gaskill, who is the wife of an army doctor, gave up a busy practice in New York to accept a commission. She was graduated from Cornell University School of Medicine in 1937. Lieuts. (j. g.) Kathryn Hyde and Dorothy Osborne have reported for duty on completion of their thirty-day training course at U. S. Naval Training School, Smith College, the former is a medical illustrator and the latter is a medical technician. Miss Hyde graduated from the University of California and took postgraduate study at Johns Hopkins University. Miss Osborne, a graduate of Pembroke College at Brown University, was a medical technician with a group of New York physicians before entering the Women's Reserve.

Because of the critical shortage of tin, the U. S. Office of Civilian Defense has been unable to procure syringes for administration of morphine by physicians of Emergency Medical Service. To meet this serious difficulty, a new device using glass and plastic has been developed.

This device consists of a small, sealed glass ampule containing $\frac{1}{4}$ or $\frac{1}{2}$ grain (0.016 to 0.032 Gm.) of morphine in solution. The solution is under sufficient pressure to eject the entire contents. A piece of transparent plastic tubing encloses the neck of the ampule and connects it to the hub of the needle. The shaft of the needle is enclosed in a small glass tube, to which is attached a stylet. At the hub of the needle within the plastic tube is a small filter.

Following is the method of using the ampule:

1. The body of the ampule is grasped in the right hand.
2. The glass tube protecting the needle is withdrawn by a twisting and pulling movement of the fingers of the left hand.

3. With the needle pointing down and the body of the ampule vertical to the skin, the needle is inserted by jabbing it under the skin.

4. When the needle is in place and with the ampule vertical to the skin, pressure is exerted with the thumb and two fingers on the plastic tubing to break the neck of the ampule. It is important that the ampule be held vertical to the skin in order that morphine may not be lost by improper technique.

5. The pressure within the ampule ejects the contents. The filter prevents glass splinters from clogging the needle.

6. When the ampule is empty, the needle is withdrawn and the whole device is discarded.

This ampule will be supplied in connection with the medical supplies and equipment that will be distributed to communities for equipping mobile medical teams and casualty stations organized in the Emergency Medical Service. The actual distribution of the morphine supply will be handled by the U. S. Commissioner of Narcotics and will be primarily under his control at all times. The amount of the drug being obtained is limited, so that initial distribution can be made only to those cities in the target areas that are entitled to receive other Office of Civilian Defense supplies and equipment.

MISCELLANEOUS

HOW TO PROLONG LIFE OF
RUBBER ARTICLES

In a statement to doctors, nurses and hospitals, William M. Jeffers, rubber director, called attention to the need of conserving rubber articles other than tires. Mr. Jeffers said that all rubber articles should be as carefully preserved as tires and repaired where feasible. This is especially true of surgeons' gloves, which require very high percentages of crude rubber.

The Conservation Division of the War Production Board has suggested the following general principles for the preservation of rubber gloves, hot water bottles, ice bags, rubber sheeting and rubber tubing:

1 Clean and dry rubber goods thoroughly before storage
2 Store in a cool, dark and dry room, away from sources of heat

3 Lay rubber articles flat when storing, allowing them to assume their natural position. Rubber under a permanent strain loses its life and will set up a deformation which may cause it to crack.

4 Handle rubber goods carefully and avoid puncturing with sharp instruments or finger nails.

5 Wash with soap and water or alcohol as soon as possible after contact with oils, greases and solvents.

The greatest enemies to the long life of rubber are sunlight, heat, oils, greases and solvents. The ultraviolet rays of the sun penetrate the surface of rubber, causing it to oxidize. Vegetable oils, cottonseed oil, mineral oil, greases, turpentine, gasoline, chloroform and naphtha cause swelling and softening, making rubber more susceptible to mechanical damage.

SURGEONS' RUBBER GLOVES

Surgeons' rubber gloves are usually discarded because of tears, cuts or punctures which occur before the rubber has deteriorated. All possible precautions should therefore be taken to reduce the possibility of such damage. Insist that gloves be put on and removed carefully and caution all wearers to avoid cutting or puncturing the glove. When drawing on or removing a rubber glove, care should be taken that the finger nails of the person holding the gloves do not tear into the rubber. Surgeons who literally "rip" gloves off their hands and throw them aside should be made to realize that this is unwisely wasteful during the emergency. Gloves should be rinsed in cold water after use and before removing them.

Proper sterilization procedures will extend the life of rubber gloves. Several hospitals have reduced the period of exposure in the sterilizer from thirty minutes to fifteen minutes.

Because of the high quality rubber, it is necessary that rubber gloves be repaired where possible and their life extended to a maximum. Cuts, tears and punctures can be repaired by applying a patch of thin sheet rubber with rubber cement. The cuffs of discarded gloves or thin rubber sheeting can be used for this purpose.

MOLDED RUBBER GOODS

The water used in a water bottle should in no case have a temperature higher than 140 F. Boiling water ages the rubber. A water bottle should be filled to two thirds capacity with hot water. The bottle should then be squeezed to expel the air in the bottle and the stopper inserted. There should be no air in the bottle when in use. After use, these items should be thoroughly drained and dried. If an antiseptic or other solution has been used, they should first be rinsed out with clean warm water. Before storing they should be inflated so that the sides will not stick together.

SURGICAL TUBING

Clean and rinse rectal tubes thoroughly and then boil for two minutes. Stomach tubes should be rinsed and thoroughly cleaned and then soaked in a 5 per cent solution of cresol for one hour. Clean tubing as soon as possible after use, and when storing allow them to assume their natural position. There should be no sharp bends or kinks.

A NONINJURIOUS SUBSTITUTE FOR GLYCERIN IN
LUBRICATING JELLY

The shortage of glycerin and gums has made it difficult for doctors in hospitals to obtain adequate supplies for lubricating gloves, catheters and other surgical rubber products. The

Canadian Hospital Council requested the Ontario College of Pharmacy to develop, if possible, a product which would not require either glycerin or gum. Such a product was developed by D. E. MacKenzie, assistant professor of pharmacy in the Ontario College of Pharmacy. The method of preparing material was described in the July 1942 *Canadian Medical Association Journal*, which stated that the following formula would meet these requirements:

Starch	7 ounces 13½ grains
Distilled water	1 gallon
Sodium lactate (60 per cent)	90 fluidounces
Mercuric oxycyanide	280 grains

Dissolve the mercuric oxycyanide in part of the distilled water, using the remainder of the water to form a smooth paste with the starch. Combine these two portions with the sodium lactate and heat in a steam kettle or some other device capable of supplying a temperature of approximately 100 C. The heating, with moderate agitation, is continued until a translucent jelly is formed, at which point the product can be at once transferred to suitable containers.

STERILIZATION

The product is best sterilized after it has been placed in containers and, following latest approved procedure, can be successfully rendered sterile by autoclaving at a steam pressure of 10 pounds (115 C or 240 F) for a period of thirty minutes.

The War Production Board states that by taking proper care of rubber goods it is often possible to extend their useful life by 50 per cent.

THE NATIONAL ROSTER OF SCIENTIFIC
AND SPECIALIZED PERSONNEL

Senior and graduate students of chemistry, physics, engineering and other specialized fields were urged, November 24, by the National Roster of Scientific and Specialized Personnel to register with the roster, writing to Dr. Leonard Carmichael, Washington, D. C., the director, mentioning the fields in which they have training or knowledge.

Registration with the National Roster is not to be considered application for employment, although many of those registered have received offers and 140,000 men and women have thus been referred to prospective employers, particularly to aid in war production and research. Many industries needing technicians consult the local USES offices. The National Roster is constantly used to advise selective service boards about the importance of work being done by civilian technicians of draft age.

The National Roster, which is a part of the War Manpower Commission, has listed and punch-card-indexed more than a half million names in more than sixty specialized occupations covering everything from genetics to housing and radio broadcasting. The names filed include the most famous scientists in the country as well as the most recent college graduates in the various scientific courses.

USE OF EMIGRE PHYSICIANS

In a release from the National Committee for Resettlement of Foreign Physicians, 139 Centre Street, New York City, Dr. Tracy J. Putnam, vice chairman of the committee, states that the standard set by the Procurement and Assignment Service (*THE JOURNAL*, October 31, p. 703) clarifies the way for greater use of this group of physicians at a time when the nation is short of trained medical men. The public now will appreciate, he said, that although emigre doctors are eager to serve with the military medical services they cannot do so and that the full use of their skill and training must be in other areas where emergencies exist and where they can serve on the basis of temporary placement for the duration of the war. The National Committee for Resettlement of Foreign Physicians has already placed fifteen hundred refugee physicians on hospital jobs throughout the country, where they serve as interns, resident physicians and in laboratories. The maximum use of the six thousand emigre doctors in the United States however, is yet to be realized.

ORGANIZATION SECTION

OFFICIAL NOTES

ANNUAL CONFERENCE OF SECRETARIES AND EDITORS OF CONSTITUENT STATE MEDICAL ASSOCIATIONS

Held at American Medical Association Building Chicago Nov 20 21 1942
Dr Harrison H Shoulders Nashville Tenn Presiding

MEDICAL MEETINGS AND MEDICAL EDUCATION

COLONEL IRLE W RANKIN

Medical Corps United States Army President of the American Medical
Association Chief Consulting Surgeon to the U S Army

The example of the American Medical Association in postponing its 1943 meeting has been followed by most of the larger medical and surgical societies in this country. Increasing transportation burdens make it especially difficult for a sizable audience to attend any medical meeting to which representatives of all sections of our country are eligible. In addition, the problem of formulating a satisfactory and progressive program is becoming increasingly complex owing to limitation in the choice of subjects imposed by the fact that so many of the leaders of the profession are already serving with the colors and therefore are unavailable. That medical meetings as a part of medical education are essential, and that they should not be completely abandoned, is an obvious fact. On the other hand, a reduction in number of meetings and a modification of programs seem a necessity until the present emergency has passed. In consequence, it has seemed to me advisable again to urge consideration of multiple small medical meetings, preferably under the sponsorship of parent organizations, to be held in various sections of the country at properly spaced intervals throughout the year. The already organized postgraduate assemblies held in numerous cities under the auspices of the local medical organizations constitute nuclei for a plan. Such assemblies could, I believe, be expanded with little difficulty into meetings which would embrace even wider territorial reaches than they have in the past. These thoughts seem to be at least worth presenting to you, they represent practically identical ideas which I advanced to the House of Delegates of the American Medical Association at its last meeting in Atlantic City. The Board of Trustees has appointed a committee to investigate the possibilities of the parent organization fostering sectional meetings in the near future and I feel that it would be most advantageous to have the reactions of the respective state units to such a proposal.

One other thought comes to me and that is the idea of having joint state meetings participated in by two or three or even more, contiguous states. These meetings have been tried occasionally. I have attended some which were a success from every point of view, and it seems entirely possible that this plan might be an acceptable departure from the usual routine of the state medical meeting. With transportation facilities being constantly allocated for troop movements with more and more men being drawn into the services, and with those men who are serving industry and the civilian population becoming more busily engaged and finding it a greater hardship to get away for any purpose, it is obvious that the curtailment and consolidation of medical meetings is a necessity and something which should be definitely planned for. I believe it would be a grave error to abandon all medical meetings, but the exigencies of an emergency compel modification of our accustomed methods and schedules.

MEDICAL EDUCATION

Medical educational standards must unquestionably be maintained at their present level as long as is compatible with emergency conditions. The production of doctors in present day quantities is an absolute must on the list of essentials. We can ill afford to give up, save only under the compulsion of necessity, our present teaching schedules. That they are being modified and that teachers under 45 years of age are being replaced in all medical schools is a tribute to the profession's patriotism and understanding. I believe that the vast

majority of medical school faculties have been eminently fair in the release of many of their younger men and in arranging for their replacement by over-age or physically disqualified individuals. I would counsel tolerance and patience in this process, for a hurried readjustment must lead to confusion and ultimately will be detrimental to the over-all program. It should also be remembered that schools differ as to individuals, and that an institution situated in a small city without a large available professional reserve to draw on for replacement of clinical teachers is more handicapped in making its adjustments than is a school situated in a large urban center. The acceleration of the curriculum has placed an even greater strain on faculties of medicine than formerly and this should be recognized by the agencies procuring doctors for the armed forces. Moreover, many medical schools are at this time engaged in research problems directly associated with the war program, and such contributions should be interfered with as little as is consonant with a complete effort.

PROCUREMENT OF PHYSICIANS

The profession has responded to the call for medical men in the armed forces in a manner which has up to the present time, filled the quotas satisfactorily. That this has not been done without some confusion and many irritations is true. I would emphasize two facts in this connection. One is that the primary purpose of Procurement and Assignment was to secure men for the armed forces. Second, that phase has now passed and irrespective of differences of opinion criticisms and occasional unpleasant recriminations which have arisen in various parts of the country, the armed forces by a combination of effort on the part of Procurement and Assignment and the Army and Navy themselves, are up to the present time adequately supplied with men. Nevertheless it should not be taken for granted that more men will not be needed in the future. They definitely will be needed by both the Army and the Navy in 1943, regardless of what modifications are made in the tables of organization for medical units. You have only to read the press reports of the Secretary of War to understand that an army of several more millions will require many thousand additional physicians and young physicians especially. In consequence, it seems to me not unfair to ask why efforts are not being redoubled at the present time in the five most populous states of the Union where physicians particularly under the age of 45, seem still reluctant to accept commissions in the Medical Corps Army of the United States.

The greatest future task facing Procurement and Assignment is unquestionably the safeguarding of the civilian health and the procuring of men for industrial plants. On the other hand, let it not be overlooked that the armed forces are the first line of defense that they must be provided for medically first. This I am convinced is the wish of every individual citizen. I can conceive of no circumstance under which a democratic nation would deny to its armed forces adequate medical care, even though it should be at the expense of other elements of the population. May I not also be permitted to recall to you the fact that the present system under which doctors are being recruited for the Army and reserved for civilian and industrial practice is a voluntary one. This fact has frequently been lost sight of. I think and there has been not inconsiderable dogmatic discussion of reallocation of physicians and drafting of the medical profession. I think that even a cursory scrutiny of the law will disclose that there is no provision for application of the Selective Service Act to any one group of individuals to serve in any capacity, save as fighting men. Doctors cannot be drafted for professional work, until all elements of the citizenry are placed under a draft regulation, I believe that the medical profession should vigorously oppose any measure which would single out physi-

cians for draft action. The patriotism of the medical profession is unparalleled by that of any other group of individuals. We have borne without reluctance and with patient tolerance, threats and recriminations by individuals, committees and commissions and yet have continued to respond to the nation's call. Do we not deserve more commendation and cooperation, and less castigation and malicious innuendo?

THE RESERVE MEDICAL OFFICER IN THE WARTIME SETUP OF THE NAVY MEDICAL CORPS

REAR ADMIRAL ROSS T MCINTIRE

Medical Corps United States Navy the Surgeon General of the Navy

During the year that has passed many years have passed when measured by the advancement of surgical methods in caring for war casualties. Pearl Harbor will always be a watchword and a symbol for the Navy and for the American people. Pearl Harbor marked an advent of modern war medicine. On that date, December 7, 1941 the Army and the Navy lost several thousand men. These men had no opportunity to protect themselves from the enemy who made the dastardly attack but they have served their country as well as any of the men who fought in the Coral Sea, at Midway and in the Solomon Islands. These men sacrificed their lives in a sudden and shocking fashion, but by so doing they brought sanity to a nation that was fast asleep and had very little unity in it.

At Pearl Harbor hundreds of men were horribly burned and we learned quickly that our newer methods were good and we also learned as quickly, the mistakes that we made. Consequently thousands of lives will be saved to the nation and to their families because of the knowledge gained in caring for the wounded at Pearl Harbor.

The Medical Department of the Navy has been planning for eventualities since September 1939, for to us it was inevitable that war would some day come on us. So in our planning we were determined to be ready to meet any emergency that might be brought on us in any part of the world in which the Navy might possibly be.

The Medical Department of the Navy has a rather peculiar duty to perform, for it serves the Navy and the Marine Corps. When we speak of the Navy it seems all of its branches, for we have our ships at sea, our aviation, our submarines and all of the hospitals that are scattered throughout the continental limits and in our far flung islands. This means that the Medical Department must be prepared to serve on board ship, on hospital ships, with the Marine Forces ashore and with our aviation wherever it may go.

To meet these demands the Medical Department of the Navy had visualized the great expansion that would surely come and found it was correct. Knowing this, to build up carefully a competent Reserve Corps, it organized dozens of specialists' units to work out screening methods which would keep out the mentally unfit. To do this it was necessary to secure the aid and assistance of civilian specialists. It is a matter of record today that the specialists and general practitioners alike have answered the call and are functioning smoothly with the regular organization of the Medical Department. It is interesting to note that there are three times the number of medical officers on duty that there were in 1917-1918.

In the last war the problem we had to face was one of serving our ships at sea and caring for the Marine Corps needs. Aviation, being in its infancy, required very little in the way of medical attention. Today the reverse is true. Aviation, with its ever growing personnel and the emphasis which is being placed on it as the offensive weapon of this war, is calling for more and more qualified medical officers. During the years between the wars very little was done in the way of sane research that would improve flying conditions for our pilots. In fact, research in general was carried on in a rather superficial fashion. Not so with our enemies. Germany as we well know, for at least five years before her attack on Poland had been carrying on intensive research in the field of aviation as well as in other methods of warfare. Consequently her planes and pilots are able to fly at consistently greater heights than ours. However, in our crowded months we have made considerable progress, but because we waited so long our months must be crowded, and the coming months must also be, if we are to attain the necessary goal whereby our pilots will be made safe in flying at heights of 40,000 feet and more.

There are times when we look at the field of research and view its enormous scope that it gives us a feeling of utter helplessness. So we in the Navy are shutting our eyes to many of the problems that we would like to see solved and are open-

ing them to certain definite problems that must be solved if we are to gain a real advantage over the enemy.

Let me enumerate some of the things that must be solved. First and foremost, shock. To you this is an old story, but it is one that should challenge your attention, for it is a problem that has not been solved and, until it is, the lives of our men who are on the front line of combat will be exposed to a greater percentage of hazard. We think we know the cause but we must find means of preventing it. So we are hard at work finding newer and better means of combating and preventing this very deadly enemy. However, with the use of our blood substitutes we have a valuable means of helping to combat shock.

The second, and very nearly as deadly to fighting men, is the specter of fatigue. It is insidious in its approach and slowly numbs the senses of the fighting men. Here is another definite challenge to you of the medical profession. What is fatigue? Until that can be answered, the goal of how to prevent it cannot be reached.

It has been our boast that the specialists in naval medicine approach their problems from the preventive side. We do, and it is with great embarrassment that we must admit that there are certain things that prevent us from always carrying out this policy. Therefore we will strive even harder to find the answers to these two biggers, but we shall need your help.

When this war began there were less than a thousand regular medical officers in the Navy Medical Corps. Today we have added between six and seven thousand reserve officers to that number. It is with peculiar satisfaction that I am able to tell you today that the great majority of these men are functioning as smoothly as though they had been in the Navy for years. It is the present policy of the Medical Department of the Navy to order as many of these officers as possible to our naval hospitals for a period of time following their induction into the service. If this cannot be done they are ordered to our large training stations, where they receive a short period of indoctrination in the ways of Navy life.

The medical specialists units that have been organized during the past few years have proved of great value in that they are now operating in our hospitals within the continental limits in our mobile hospitals that are established in the islands of the oceans, and on our hospital ships. The officers of captain and commander ranks in the regular corps of the Navy are being used in executive capacity, in the main, and the professional work is being carried on by our reserve officers. We find that this works in a highly satisfactory manner.

Up to this time we have used regular medical officers on board ship for it is difficult for a civilian to enter such a highly organized life and be able to function as a part of it. We are now finding, however, that it is possible to place reserve officers on board our ships who have had several months' duty in our large shore hospitals. I am also able to tell you that we have been and are making every effort to see that a medical officer who is especially qualified—in surgery, urology, x-ray—is given an opportunity to carry on that work if he is on shore duty. If, however, he is on sea duty he then must again assume the role of a doctor of medicine. It is a great satisfaction to me to be able to say here today that the average specialist who has found himself thrown in a field where it was necessary to practice medicine in all its phases has delivered the goods in a grand fashion.

I want to tell you a story about one of our outstanding specialists in a certain line, who entered the Medical Reserve Corps of the Navy some two years ago. He could not believe that it was possible for the Navy to carry on its work in the field unless it was done so by specialists. I assured him that we were very glad to have him in our service, that he would fill a very needed spot and that he would be used for the time being in his specialty. I advised him to spend some of his time in the hospital to which he was going in seeing what the surgeon was doing, to refresh his mind in x-ray diagnoses of other conditions than his specialty, to be able to look in an ear and to examine an eye ground. He looked at me in a rather doubtful fashion and said "I do not believe I can do it." The other day I happened to see this man and he was having a fine time for in addition to being of great help by reason of his years of experience he was now having an opportunity to see sick and injured men again, with any number of conditions that he would never have met had he stayed in civil life.

It is my hope that we shall never see medicine in this country subsidized by the government. I do believe, however, that the government can, and should help in any way it can to reduce hospital costs. By providing means to reduce the fees that come from all kinds of laboratories and specialized examinations would be a legitimate means of government aid. The doctor must give thought to, and how, his part can be played.

in this, and here the matter of specialization will need to be given serious consideration.

It is again my hope that in the very near future the troublesome problem that is now before us, as to the proper spread of medical personnel throughout this country, will be adjusted. The Medical Department of the Navy has no expectation of asking for any more doctors than it actually needs to carry on its part in this war. It expects to play its part, regardless of the numbers that may be available, and should it be necessary to go below the standards we believe we need we shall do this rather than cause hardship on the industrial output of this nation by reason of epidemics that might be due to lack of proper medical supervision. It is my thought, however, that when this whole field is properly worked over, and authority is given to handle personnel, we shall not come to any such end.

We have today forty one naval hospitals ranging from bed capacities of 300 up to 5,000. The smallest hospital we have today has a patient load of 175, and the largest has just short of 3,500 patients. Those hospitals are being run by the people from your ranks and they are doing a grand job. We keep a very few regular officers, a commanding officer and an executive officer—probably one or two more, perhaps one or two retired officers who help on the administrative side. You all know that a reserve officer has to have some time to get on to our method of doing things the old routine that must go on. For that reason we do keep a few of our regular officers in these institutions but every one of our hospitals is staffed in that fashion.

The specialists units that we organized years ago, and have kept organizing as we have gone along, have been very valuable to us. Now we are sending these men out into the field. They are in our large mobile hospitals, they are on our hospital ships. We are finding now that we can put these young men on our destroyers after they have had a year's duty in the service. And so throughout the entire world we have reserve officers operating in the active units of the fleet and I think that is a very high compliment to the civilian doctor.

I am not going to invade Dr. Lister's field to any extent in this, but I want you to know he is doing a grand job and his committee right with him. The Navy has and is making a hard and fast rule that we take no doctor into our service unless he has been passed by this committee, and we expect to continue that. If the voluntary system is going to work at all it must work in that way.

In the last war the problem we had to face was a simple one, because we were fighting a war in Europe. All we had to do was simply look out for our ships that were in rather an easy sort of naval war. Look out for transports take care of the people in training within our continental limits and look out for a modest number of casualties.

Today the reverse is true. Aviation is putting a great load on us. It is going to put an ever increasing load on us in the offensive side of this war that is coming on. We are seeing lots of casualties in this South and Southwest Pacific action.

You are going to see one thing happen in this war that didn't happen in the last. The mortality figures will be tremendously high. But I am glad to say today that you are going to see a tremendous improvement in the care of war casualties. We are learning rapidly in this action around the Solomon Islands—and it is a violent one—that war casualties can be cared for, even though we are operating in islands that are certainly isolated. Yet we can get these men into our hospitals which are put in rather safe places, and that is due to the advance in aviation.

When I was on the West Coast a short time ago I had an opportunity to see the first of our transport planes that we are going to use in this work. They were fitted up to take 15 stretcher cases and it was felt then that they could carry 35 ambulatory cases. We scaled that down to 12 and 25. By this method we can fly these men out of the islands on the same day of the engagement. We bring them out that night, flying them several hundred miles to one of our large hospitals, where they get their operative treatment the next day, that is, if they are sufficiently out of shock to receive that sort of treatment. They are cared for there. Of the first 1,000 of these cases that came in the mortality rate of these war casualties, head injuries, chest injuries, abdominal and all, was less than 1 per cent. That is a tribute to what medicine has done.

You would be surprised if you knew how they give blood plasma on Guadalcanal. They don't even bother to take a man into the dressing station or the collecting station. They can do it right out in the field and do it well. The wounded are given their morphine, and they are given their plasma if it is needed, they are given their first aid measures and sulfon-

amide drugs liberally. Then they are moved when they can be moved to a collecting station, and the next operation comes as soon as they can be flown out.

The operation now on Guadalcanal is not all being conducted by marines. We have a large group of the Army fighting right along with us. What I am saying does not go for just us, it goes for the Army as well. It is a fine record of accomplishment.

Research must go on but we are being faced day after day with problems that are such that call for rather rough and ready research the practical side of it, such as finding the answer to the underwater blast. That is giving us more concern at this time than any other one problem we have in the Navy. We are losing lots of ships at sea. These destroyers that go in and come under point-blank fire go down fast when they are hit and the men are left in the water. When a destroyer sinks the depth charges, which are always there ready to be thrown on the enemy will explode when they reach a certain depth. There is no way we know to keep that from happening. When this occurs, rather terrible things happen to the men who are swimming in the water. That is bad for the morale of the men who are attempting to rescue them, they see death come to men who are just 50 or 100 feet away. Research is going on in this problem, and also in the air blasts from bomb explosions, but slower progress is being made there.

We have found mechanical means in the short period of three months whereby we can protect the chests of men who are swimming in the water if we can get the body high enough out of the water. We are going to save a lot of lives by that rather rough and ready means. We still haven't perfection, not by a long way but research is going on.

We can all feel proud of the great part that blood plasma and now human albumin are playing in combating shock. We in the services have a great hope that in this year the answer will be found to be bovine albumin. There is some interesting experimental work going on some vital work, but there seems to be one little step in the process that has not been cleared. It will be a little time before the National Research Council is ready to pass its approval on the bovine albumin. But the human albumin is working, and working well, and we are now supplying it to ships at sea.

This war is so violent in its form owing to the tremendous bomb loads that are being carried by planes and the size of the bombs, that when a bomb goes through into a ship and explodes somewhere down in the lower levels the most peculiar forms of injuries develop.

I want to give a lot of credit to the two or three committees of the National Research Council of our Medical Section for the fine work they have contributed on compound fractures. It has been of great help. The use of sulfonamide drugs in combination with sensible treatment is doing a great deal to bring about the saving of lives especially on our aircraft carriers. I could tell you stories that would make you weep of the terrific jobs these medical officers have been faced with on these big aircraft carriers. They are the ones that are attacked, and attacked violently. In a few instances doctors have had just an hour or two to get their sick and wounded off and yet without exception on the aircraft carriers that have been lost, there was not one wounded man left on board a ship. The results have been so good that it doesn't seem we could continue to have such splendid luck.

When this war is over our doctors are coming back to this country. There will be thousands and thousands who will go back into civil life because the Army and the Navy will shrink, as they should but I hope never to the point they did before. These men are coming back with an entirely different slant on a lot of things. I think we must be careful that they do not come back with the idea that they can practice only one form of medicine. Specialization—yes, we must keep it. But I feel that this organization has a duty to do. It should be the guiding body in specialization in this country.

That brings me to the point of the cost of medical and hospital care. I hope the time never comes when the practice of medicine or anything that has to do with it, has to come under government control. I think it would be a disaster to this country, it would be a disaster to medicine. When this war is over money is going to be a scarce article, it is going to be scarce with all of us. This war is going to be mighty tough on all pocketbooks. When this is over the man who makes \$1,400 a year or \$1,800 or \$2,000 is still going to have his family to support. What are you going to do about that group? What are we going to do about the cost of hospital care? How can that man go through a period such as we are going to have without question for ten years after this war finishes?

I am not a pessimist about this, I think it can be done. I believe medicine should start thinking constructively today on that subject. I don't think we should allow organizations that are not competent to dictate to us but unless we have something sound, so that we can lead the band down the right street and out of a blind alley, we are likely to have something like that shoved on us.

I hope you will give serious thought to this. I do not have the answer at this time. I have some ideas. You are a representative group. You have had years of experience. You see things happen in all sections of the country. Let us be about it, and let us see what we can do.

A lot will be said here today about redistribution of doctors in this country. A lot will be said about the proposition of getting people to move from one place to another. We have no way, as Dr Rankin has said, to go into New York City, where there are plenty of doctors and say to John Jones "Out in Nevada the Army and the Navy have taken practically all the doctors and there is a very fine opportunity." This man will say "But I don't like Nevada," and that is all there is to that. I wonder how we can make some of the sections of the country attractive enough to a lot of the people who can't go into the military services. I wonder how we can find ways and means of utilizing some of our surplus. I know it is difficult to ask a man who has an established practice to go out into a section of the country and work there two or three years and then possibly be faced with the problem of a man coming back who has been there all his life.

There is another knotty problem. I feel rather sorry for the Surgeon General of the Public Health Service because he has that problem. We in the Army and the Navy have the easy job if you please. We have the job of seeing that men get through this war with the least trouble possible and we are going to do it. Why? Because we have been given the tools with which we can work.

On the civil side of this picture there is little that can be given at this time. Without active cooperation from every organization we have today we are not going to get the things that will be necessary to care for certain sections of this country should we fall into the large epidemics that seem to go along with mass troop movements.

I want to express again the appreciation of the Medical Department of the Navy to the members of the American Medical Association. After all, the Navy Medical Corps is a part of you, and you certainly are a large part of us. We are going to do everything we can, as this war goes along to give you the benefit of the experience we gain day by day in the field. We are not going to hold up any information that we think we should give out or that we think has been proved to be of value. Fortunately, we have our Division of Medical Sciences of the National Research Council, which is of tremendous value. All of us appreciate the sacrifice every man is making and the time he has given during these past two years. I have an opportunity to see a lot of it. I don't know how they do it. I think they must quit work at home. I don't see how they are able to be in Washington giving us the help they have given us.

I am in complete agreement with the President of this Association that medicine should be given a tremendous amount of credit. But I want to go one step further. Let us go ahead and let us do enough so that our critics will be completely confounded and there will be no opportunity for them to point a finger at us in any way, shape or form.

WAR PROBLEMS FOR MEDICINE

FRANK H. LAHEY, MD

Chairman Procurement and Assignment Service for Physicians,
Dentists and Veterinarians

I should first express the appreciation of the board to so many men who have participated in Procurement and Assignment, who have played such a great part in whatever it has accomplished up to now. It seems to me I should call attention also to the fact that, as becomes medicine, Procurement and Assignment has not sought publicity to advertise its accomplishments. Perhaps it has been unduly modest in not seeking publicity as relates to its accomplishments.

In spite of the fact that every member of the Procurement and Assignment Service went to Washington with considerable apprehension about how it could function with governmental agencies, every one has been pleased and gratified. Mr McNutt has been delightful and a most satisfactory person with whom to work. It is always possible to get direct action and prompt action. His understanding sympathy with our problems has been a source of great satisfaction to all of us. I don't know what the Procurement and Assignment Service

would have done without Mary Switzer. Mary Switzer is a coordinator extraordinary. She knows every one in Washington. She has a most comprehensive grasp of many situations, and she is apparently trusted by every one who deals with her. She understands, I believe, many of the problems of medicine which have disturbed us, and she has a clear and practical understanding of them.

We should not fail to realize what Dr Leland has done. Dr Leland has literally contributed his health to this undertaking. Without the figures he has obtained for us, and the work Major Lueth has carried on so efficiently, the undertaking would have been nowhere near as successful as it is today.

All the offices of the American Medical Association, and its complete resources, have been placed without limit at the disposal of the Procurement and Assignment Service. Olin West's advice and Morris Fishbein's guidance in many problems have been so helpful that I am sure I speak for the board when I say we recognize them with great appreciation. I am fearful lest you think this is a eulogy but, after all, this is the time to speak about how these things have been accomplished.

One of the things I had to deal with was the Budget Committee. It is intangible and we must not be irritated with it. It is the apprehension in Washington that the American Medical Association pulls the strings. At the Bureau of the Budget you have to answer the question: Is this all controlled and prompted by the American Medical Association? We should not be too sensitive and gun shy about it. Nowhere I am certain has there been, as far as I can see, any obstruction or lack of willingness to cooperate in every way.

There is not a member on the board who wants a thing for himself except to make a contribution. I think I can say to you that this board represents peculiar qualities. Whoever picked it out, I am sure, never had it in mind, but the members of the board have qualities which are desirable to make the group work well, and they have harmony. There is no discord.

The corps arcs and state chairmen I pass over with thanks, because I think they are appreciated.

But let us go to another group that is not appreciated, the lower group who do the spade work. They are the sisters, that is, the district and county representatives. They do the personal intelligence work. They are the men, I think, who will not get the reward but who really play such a large part and have played such a large part.

Colonel Seely really pioneered this, and he put his life and soul into it. He worked late hours, Sundays and holidays and traveled the country.

The Procurement and Assignment Service did not have an easy job making as it did, four moves within nine months. I wanted to write an editorial—the board thought it was a little too freetious—that it would be a good plan, since we were moving every other month to get a fleet of trucks, set the girls and officers and typewriters up in the trucks, and we could really accomplish more than we could by carrying records upstairs and downstairs. Now that has all been settled.

I am, in addition, anxious that you understand how cooperative Selective Service has been. General Hershey is a fine man to deal with. He thinks straight. He has a homespun philosophy that is wholesome. Colonel Eanes Leonard Rowan and every one else, the Army, the Navy, the Public Health Service and all the branches of the service have helped us. Never has it been impossible for me on short notice to telephone Generals Magge, McIntyre, Parran, the Selective Service, or any other member of the board and get prompt action, appointments and satisfactory replies. And never have they failed to express their appreciation of what medicine is doing.

This problem of quotas has been no easy one. These quotas have not been set up arbitrarily. They have been weighted and counterbalanced in relation to the urban and suburban population and the number of doctors.

The Procurement and Assignment Service had to set up priority obligations. As Colonel Rankin has already said, the priority obligation has been to get doctors for the armed forces, particularly within this past year. As Colonel Rankin and so many in Washington have said, the war does not end on January 1 just because we meet our quotas. What are we going to do about these states, including my own, that have not met their quotas? What are we going to do with California which has met only 81 per cent of its quota? What are we going to do with Connecticut which has met only 76 per cent of its quota? What are we going to do with Illinois, which has met only 82 per cent of its quota, and Massachusetts which to my blushing shame has met only 78 per cent of its quota? If Massachusetts considers itself the Cradle of Liberty, it

should hide its head in shame. What are we going to do with Nevada—less important, perhaps, because it represents such a small number of doctors—with only 65 per cent? And New York so distressingly only 78 per cent? In New York three nights ago some one in the audience said "The reason so many Southerners are in is because they don't make enough money in their jobs, and they live in rural communities where half of their population is colored, and they had rather be in the Army." If you make any such statement when you are under the quota it is an apology and not a reason.

The priority obligations of the Procurement and Assignment Service have been

1 Supplying the doctors for the armed forces. That was easy, because we have had literally a surplus, but it will not be as easy next year.

2 The evaluation of needs. What is the figure of dislocation of people—perhaps not 5,500,000? How many doctors have to be dislocated? Perhaps 3,500, perhaps only 2,000, but at any rate a good many.

The next priority need is the evaluation of dislocation and then how to dislocate them. There are other problems, such as the economic problems—handling them financially and seeing that they do not suffer. What about the quotas for 1943? Has there been a figure settled about what can be spared in relation to the number of doctors for 1943? Yes! What is a standard figure for the population and what are the needs going to be for the rest of the period? Is the percentage of 1 doctor to 1,500 civilian population a fair figure? I have asked the various representatives of the armed forces if they accepted that figure, at least for the present. They accepted it. How will it be handled? Prorated, obviously. What will be the relationship to the states that have run over their quotas? As would be expected, there will be credits to the states that have run over, and there may even be states from which no men may be asked if they have run sufficiently over their quotas. Already two hundred and eighteen physicians have been located in one hundred and fifty-four different communities in twenty-nine different states.

Let us also have in mind some of the obstructions to progress in the war effort which have been depressing me. State licensure has been depressing. When states' rights on such a simple thing as dislocation of a doctor can obstruct meeting a problem such as this it denotes no other thing than a lack of realization of what the real war problem is.

Let us give credit to the U. S. Public Health Service which, at the request of the Procurement and Assignment Service, has completed tables for each state showing distribution of physicians by counties, classified by section, race, specialist, general practice, those in full time positions, also population per physician and per private practitioner over 65. Comparable data by sampling of states is going on for 1943.

One other phase has been personality problems. In some of our states have been personalities that have been difficult to deal with. I have a formula for that which I think is good. Personality problems are luxuries to be reserved for peacetime. They are contributions against the war effort, and not contributions for it.

Because we have had a dislocation problem in the state of Oregon, because we have a representative of the state of Oregon here who has met this problem, who has to leave this afternoon, because they have met it so satisfactorily that it might even be a suggested pattern for others who have to meet it, could we hear from him briefly on how they have met this problem in relation to the Kaiser shipbuilding problem in Vancouver, Washington?

DISCUSSION

DR JOHN HAROLD FITZGIBBON, Portland, Ore. Our problem in the Pacific Northwest is different, no doubt from the problems elsewhere in the country. I am not advising you that our solution will be the solution to any of your problems. Perhaps our method of study may help you to arrive at a solution of your individual problems. The shipyard problem in the Pacific Northwest is not limited entirely to the Kaiser interests. The Kaiser yards have received the most publicity and are turning out the most ships and the fastest production. There are in the Portland area, in addition to the yard at Vancouver, Wash., and two Kaiser yards in Portland, several other small shipyards that are employing a vast number of men and women. The Washington problem and the Oregon problem are interrelated, as far as Vancouver is concerned, because Vancouver might almost be considered part of Oregon if it were not for the state line. It lies across the river from Portland, and the bridge between the two cities makes them almost one metropolitan area. However, the Vancouver problem is entirely different from the Portland problem, because Vancouver is a smaller

city of about 22,000, with twenty to twenty five physicians, about one third of whom are now in the armed forces, leaving a definite shortage. In Portland proper we have a medical center with a medical school, a large number of physicians, a metropolitan area which must be taken care of, plus patients who come from a distance in all directions.

There have been remarks in the press recently about the Vancouver situation which I feel are entirely unjustified. I know they are unjustified because the comments made were due to misinterpretation of Procurement and Assignment directives which were issued and which were followed by the Washington Procurement and Assignment men. In Oregon, when the Kaiser interests opened, a demand was made that the physicians take the Kaiser employees, their wives and dependents, on a family coverage basis. We were told that this would be done—or else! We did not know just what the "or else" implied, but we did know that it implied the building of a hospital or hospitals locally and the importation of salaried physicians to take care of these people. As a result of the efforts of the state and county medical societies, a contract was made with the Kaiser company whereby the employees who choose to be covered may be cared for under the Oregon Physicians' Service. This is a medical society approved plan operated under the board of medical economics of the state medical society on an entirely voluntary basis. Employees who do not want to be covered are not covered. There is no salary deduction unless the employee elects to be covered. A charge of 60 cents a week is made covering hospitalization and medical care. The Oregon State Association of Hospitals takes care of the hospitalization. The Oregon Physicians' Service takes care of medical care. They are entirely separate organizations associated in this problem. The care does not cover accidents on the job. The state industrial accident commission takes care of accidents on the job and we handle only sickness. Between the state society and the industrial accident commission there is ideal cooperation, so that expenses are pooled and apportioned according to the needs. Many of the employees are covered—perhaps 30,000 or 40,000. Many, many thousands have not elected to take the coverage and are coming in as private patients. Our population normally in the metropolitan area is about 350,000. During the last year that population has increased to 450,000. Mr. Kaiser informed us the other day that additional employees are being brought in for further ways which are being laid, so that we shall have before spring an additional 90,000 to 120,000 people. We accept 90,000 as the most likely figure, which will bring our population to 540,000.

Mr. Edgar Kaiser, the son who is in charge of the Northwest yards, came to the Oregon State Medical Society on October 23 and stated his problem, his responsibility to these people, whom he considers individuals who have come there to help his organization in the war effort, and who we consider are medical responsibilities. He told us as nearly as he could what his future contracts would call for and what we could expect in the way of population load. He asked us whether we thought hospitals should be built and whether doctors should be imported. Out of this conference a committee called the Oregon War Emergency Health Committee, of which I am chairman, was appointed. This committee represents the state medical society, two county medical societies, a branch of the medical women's association, the dental association, the nurses, the licensing boards, medical, dental and nursing examiners, the public health agencies as represented by the state, county and city health officers, the pharmacists and the visiting nurses. We have fifteen different health groups represented by their own appointees on the committee. The problem was presented to this composite committee, and a chairman from each group was told to go into his own group and appoint a subcommittee to carry out the investigation and bring in a report at the next meeting. The reports were brought in compiled and discussed by the entire committee, then this working report was organized. We started first with public health. We realize that the public health phase is of the utmost importance, because the importation of people from all over the country brings all sorts of diseases, smallpox, diphtheria, malaria and we know not what else including perhaps a great deal of tuberculosis. The county society urged the state, county and city public health agencies to take steps immediately to immunize as rapidly as possible all newcomers who are not already immunized against smallpox, diphtheria and typhoid, if thought necessary, and to take measures against contamination of various kinds. One housing project alone will house about 50,000 people, which is a small city in itself in an area that has never had a physician or an office, or anything but a farm building or perhaps a fishing dock. The physicians of the city had a mass meeting—not a

society meeting, but representing all the physicians, both society and nonsociety physicians—and went on record as offering their services gratis to the public health agencies to carry out this immunization campaign. We requested the press to help us. The contiguous hospitals will be enlarged. We have from the public health men definite plans for enlarging. We know where to put the partitions, how many beds to order, where the plumbing is to be.

The problem of general hospital beds was the one we thought would be most difficult. However, the hospital association promptly brought back a statement of exactly how many beds it had, how many it had in storage, how many were ordered, how many were needed and how many rooms not containing beds could be used as hospital rooms for patients if the beds could be obtained. We found, to our surprise and joy, that we could immediately increase our hospital beds by 307, that we could, by changing one of the nurses' homes, which had been a hospital, back into a hospital and housing the nurses in barracks, add another 85 or 90 beds. By going to the county commissioners—the county hospital no longer has enough patients to keep the interns busy—we can perhaps get permission to put private patients in the county hospital and in the Dornbecker Hospital for Children. Another hospital which had been closed several years ago and made into a home for unfortunate girls who were poverty stricken—there being no unfortunate girls who are poverty stricken now—can be returned to the status of a hospital, giving another 50 beds. So out of this study we have definitely shown that we can almost immediately develop 400 additional beds.

We are making a pregnancy survey. For some reason or other, during wartime the pregnancy peak goes up, and our town is not an exception. We hope to find out how many pregnant women there are in town, when they are due, and plot a graph so the hospitals can figure on when they are coming in. We are going to try to shorten the period of hospitalization, but unfortunately we cannot send the women home because one cannot hire any maids to work in the house. They can go to the shipyards, and they say "There is no sense being a maid for \$150 a month when I can go to the shipyard and get \$250." We are going to try to get some of the nonpracticing nurses—those who are married, partly disabled or something—to take some of these mothers, after a week's hospitalization, into their homes and perhaps help them on their way for a week or two. Then we hope to be able to change insurance policies. If we can get insurance companies to change their policies, their disability policies, so that they will read, not that the fee will be paid during the period of hospitalization, but during the period of disability, which ordinarily would require hospitalization, we can get rid of a lot of people who are sitting around hospitals collecting insurance. If we can get walking cast patients out of the hospital and into boarding houses, there is no sense in an industrial accident patient sitting around waiting for weeks until his cast is taken off, when a private patient would be home. Boarding houses will have to be provided to take care of them.

At this mass meeting the question was put to the physicians "Can you do more work and, if so, will you do more work? What are you willing to do?" A written answer was requested from each man with his signature. It was unanimously agreed that the physicians now on the job could handle this increased load.

We had originally 550 physicians, or 727 persons to the physician. We have lost 150 already to military service and through death and disability, which gives us 1,125 patients to the physician. We have about 25 more men who will go into the services after processing which with our additional 90,000 people, will then give us 1 physician to each 1,500 persons. The medical men have decided that they can and they will handle the situation on a private practice basis. The first step is to request the housing authorities to do something which they have apparently forgotten, to build doctors' offices in these projects and rent them to physicians who will go in and carry on private practice. Other physicians who feel they cannot spend full time have offered to go in on a part time basis. Three or four men will agree to handle one office and keep it going full time. The other men in town, particularly those in industrial areas, are willing to carry on evening office hours. Our big problem is the day worker. We must get as many man hours per worker as possible in order to keep up production. Our swing shift and night shift workers can come in as day patients during office hours, but the day workers who stay on the job must be seen after office hours. We feel that the local men should be given an opportunity to carry out this proposed plan before we ask the Procurement and Assignment Service and have men brought in.

The dentists have not yet submitted their plan, but they say they are willing to do anything they are asked to do. The nurses have studied their situation. We are going to have to get more nurses' aides, more hospital lay workers, and change the type of nursing in the area. The nurses have suggested that if we will make some sort of arrangement whereby they can be utilized as nurses and not as janitors, maids, back rubbers, florists taking care of bouquets, telephone girls telling Mrs. Jones that Mrs. Smith is much better today, with visiting hours cut down and rugs taken out of rooms, and all sorts of frills omitted, they can get by. They are cooperating to the fullest degree, and I believe we shall have the nursing problem settled. We have the ball and we are somewhere near the middle of the field. We have made at least one first down, and we intend to keep on carrying the ball before calling for outside aid. However, if you have any men who are well qualified physicians who care to migrate, we won't frown on that. We don't care to have the men who can't make good somewhere else just come in there because there is an opportunity.

The physicians of the community have an obligation to the men who have gone into the armed forces. In a recent visit to our University of Oregon unit at Fort Riley the question asked me by the medical officers there more often than anything else was "What are you fellows doing for us when we get back? What are you doing to maintain the standards of practice, and what are we coming back to? Are we coming back to socialized medicine or are we better off if we stay in the Army?" The answer now is that we have the ball, and we are going to try to keep on carrying it.

SOME PERSONNEL PROBLEMS OF THE SURGEON GENERAL OF THE ARMY

BRIGADIER GENERAL CHARLES C. HILLMAN
Medical Corps United States Army

I wish to express the appreciation of the Surgeon General for the untimely cooperation of the medical profession of this country—the American Medical Association and its constituent bodies—to the sister services, the Navy, the Army, Selective Service and the National Research Council. Without their full cooperation, the work of the Surgeon General of the Army would have been much, much harder than it has been.

The response of the medical profession to the War Department's recruiting program has been most gratifying. To date, eleven months after the declaration of war, there are on active duty, or under orders, nearly 36,000 medical officers, the number exceeding by 5,000 those in the Army at the time of the armistice in 1918. The physicians of the country have been called on, individually and collectively, to make sacrifices for the war effort far in excess of those demanded or expected of any other professional technical or scientific group. Notwithstanding these facts the medical profession will necessarily be subjected to further demands as augmentation of the military forces, as announced by the Secretary of War, continues.

It is now over two years since the Seventy-Sixth Congress empowered the President to order into active military duty for twelve months training any or all of the officers of both reserve components, that is, the Officers Reserve Corps and the National Guard of the United States. This call was with or without the officers' consent and was, as we all realize absolutely necessary in order to make effective the National Selective Service and Training Act of 1940. At that time the Medical Corps of the regular establishment of 1,230 was reinforced by 450 reserve officers on voluntary active duty. One year later, on Dec 7, 1941, this number had been increased to 11,400. Today, as I have said, it approaches 36,000.

The immediate response of the medical profession to the national emergency was, I must admit, not very encouraging. New appointments were rather slow in materializing. By May of this year there was only a total of 13,000 medical officers in the Army to meet requirements numbering about 21,000. At that time active recruiting in all the states was begun. The response was immediate and generous and has continued so.

Few of us had ever dared think of the mobilization of an army greater than 4,000,000 men. For this size army physicians could be procured in adequate numbers without undue disruption of the medical economy of the nation. Plans for the utilization of medical officers were made accordingly. However, the computed requirements for such a service for the ever expanding army are such that strict account must now be taken of the availability of the cloth for our garment, and our pattern modified so as to fit our requirements to the maximum number of physicians who may be expected to be available for military service.

By careful planning and a 25 per cent over all reduction of our present accepted requirements, this will be possible. The Surgeon General has requested that the War Manpower Commission, acting through the Procurement and Assignment Service, make "available" additional physicians who may volunteer their services to the Army to bring the strength of the Medical Corps to military adequacy, based on the aforementioned reduced ratio, for a force of seven and one half million. This means that we must maintain our present rate of procurement of 1 000 physicians each month. I feel confident that this latter will be maintained but ask your assistance especially in procuring the younger officers whom we so greatly need, the young active physicians who may be appointed in the grade of lieutenant and assigned to combat troops, to divisions, to tank battalions, to para troops, to Air Corps squadrons.

The Surgeon General, while sincerely appreciating the loyal offer of service of the physicians above Selective Service age, realizes that their acceptance for the Army creates in civilian communities the shortage of physicians which may necessitate the deferment of the military service of the younger men. It is the duty and the prerogative of the latter to enter the armed forces of the country and to serve as did their fathers in 1917 and 1918.

Such deferment of physicians as may be considered essential to the health and safety of the community will be on the advice of the Procurement and Assignment Service to which Selective Service, the Navy and the Army turn for information regarding the "availability" of physicians for the armed forces. Applicants declared "essential" by this service are granted commissions neither by the Navy nor by the Army. Selective Service boards make use of such information in determining the occupational deferment of registrants.

Since essentiality is necessarily a relative status, the increasing requirements of the armed forces necessitate continued revision of the essential lists prepared by the state chairmen of the Procurement and Assignment Service in conjunction with the authorized representative of the state and county medical societies. From such lists the Army will be furnished the names of additional physicians who may be declared "nonessential" to the local community.

The assistance of the Procurement and Assignment Service has been of inestimable value, its active participation in the War Department's recruiting program has not only made it possible to procure the large number of physicians required for the military service but also prevented the absolute confusion and the disruption of civilian medical service which I am sure would have resulted from indiscriminate recruiting and uncontrolled appointment.

Every effort has been made to effect appropriate assignments of medical officers. In occasional instances errors have been made, in others it has been necessary knowingly to assign individuals to duties which failed to utilize their professional attainments. However, a determined effort has been made to relieve physicians from administrative and other nonprofessional assignments and to restore them to their role of doctors caring for the sick and injured. It is believed that a short review of the training program of the Medical Department as it has been developed to fit medical officers better for their particular assignments and to train nonmedical men to fill ancillary positions in medical facilities will be of interest.

TRAINING OF MEDICAL OFFICERS

No distinction has been made in the training of Regular Army, National Guard or Reserve officers. Officers of all components have been equally eligible and have attended the same courses. Training facilities have been made available by expanding existing Medical Department special service schools, by the establishment of new schools and by utilizing training facilities in civilian universities and in industries. The Surgeon General has as far as possible held to the fundamental concept that (1) junior officers not yet specialized should be given thorough basic tactical instruction on entrance in the military service and later be assigned to the field forces, thereby reserving fixed hospital service to members of affiliated units, limited service personnel and highly specialized officers of older age, (2) that Medical Corps officers should be relieved from all administrative duties wherever and whenever possible by officers of the Medical Administrative Corps. To implement this policy, the facilities of the Medical Field Service School have been tremendously expanded, Medical Administrative Corps officer candidate schools with a current entering quota of one thousand three hundred each month have been established, and tables of organization have been revised to place Medical Administrative Corps officers in all possible admin-

istrative positions, thus reserving to the Medical Corps officer professional activities. As a result, at no time in Medical Department history have so many varied duties been assumed by the Medical Administrative Corps.

The procurement objective for Medical Administrative Corps officers as of Jan 1, 1943 was slightly over eight thousand, which means that an equal number of doctors will be spared to duties which may be and are being done by lay personnel. As a specific example, in one of our large medical replacement training centers the total allocation of officers to this center is four hundred and ninety seven, only ninety-three of whom are of the Medical Corps and four hundred and four of whom are of the Medical Administrative Corps. The few Medical Corps officers present are pooled and utilized to teach only the technical subjects.

Facilities at the Medical Field Service School at Carlisle Barracks, Pennsylvania, have been expanded from sixty officers a year in 1939 until it is now possible to accommodate either one thousand five hundred officers at one time for six week courses of instruction or seven hundred and fifty officers and seven hundred and fifty officer candidates. Flexibility at this school may thus be exercised, depending on the requirements.

The training facilities of the Professional Service Schools, Army Medical Center, Washington, D C, have been expanded from approximately seventy-five students yearly capacity in 1939 to a number in excess of one thousand five hundred at the present time. Special emphasis is being placed on training in tropical medicine, the facilities providing for six two month sessions, each accommodating two hundred students, making a total of one thousand two hundred trained in this subject annually.

The course in Roentgenology which has been maintained at the Professional Service School with an entering quota of fifty each month is being moved Jan 1, 1943 to the University of Tennessee Medical School, Memphis, Tenn, and will be expanded to accommodate approximately one hundred officers and one hundred enlisted technicians.

The Medical Department has currently authorized pools for a total of eight hundred officers at general hospitals, where they receive basic military and hospital administrative training. Circular Letter No 48, S G O, prescribes the training program to be utilized. Parallel job type of training is utilized, that is, potential executive officers actually understudy executive officers for one to two months. The medical replacement training centers and the medical field service school are also authorized a total pool of five hundred officers. Newly commissioned officers at these installations receive basic military and tactical instruction for one to two months. In addition they have an opportunity for applicatory exercise in command functions, since troops are readily available. These individuals are then considered as suitably trained for field assignments.

Prior to July 1942 the restriction in the National Defense Act prohibited the Army sending other than Regular Army officers to civilian institutions. This restriction eventually was removed and each branch is now permitted to send to civilian schools up to 2 per cent of its commissioned strength at any one time. Through the extensive surveys and recommendations made by the various subcommittees of the National Research Council, the Surgeon General has submitted a definite program of civilian institutional training in the professional specialties to the War Department for approval, secured the necessary funds, executed the required contracts with the universities concerned and set this program into operation. The Surgeon General acknowledges great indebtedness to the Division of Medical Sciences of the National Research Council for its earnest cooperation and assistance. Without this assistance the initiation of these courses would have been difficult or impossible.

In order that Medical Corps officers may be conserved for professional duties, schools for medical administrative corps officers have been established and expanded until one thousand three hundred are entering these schools each month and approximately one thousand one hundred will graduate each month. The course of instruction is of three months duration. These schools not only serve to conserve Medical Corps officers to professional duties but afford every enlisted man with the requisite leadership qualifications an opportunity of becoming a commissioned officer.

The appointment of sanitary engineers, laboratory specialists, nutritionists and other scientific and technical personnel in the Sanitary Corps is likewise making possible not only a better medical service but also the economic reassignment of medical officers. I assure you that economy in the use of physic in the military service is being carefully planned.

Let us turn for a moment to our overseas hospital units, especially our numbered general hospitals. You are all doubtlessly acquainted with the groups of integrated officers and nurses which have been organized by outstanding hospitals and medical schools throughout the country—our affiliated units. Despite the administrative difficulties of their organization and the confusion which only too frequently resulted from their peculiar status, the fundamental result has thoroughly justified the Surgeon General's action in again adopting the scheme of sponsored units which was so successful in 1917 and 1918. General and evacuation hospitals organized by these schools and hospitals are now in all of our far flung theaters of operation. Others now in training are awaiting departure overseas. Sixteen have not been ordered into active duty, their personnel having remained available to the school or hospital, and to the civilian community, awaiting economical utilization in the military service. When these remaining units are finally activated, we must organize a great many more, not from physicians in civil life but from those already on duty and from newly appointed medical officers. It is not contemplated that the principle of affiliation will be extended.

Before closing may I touch briefly on an aspect of our personnel problem which, while principally a provision for the future of the Army, is a present perplexity for you. I refer to the significance of the lowering of the Selective Service age to 18 years to medical education.

As you know, adequate provisions have been made for students now actually matriculating in approved medical schools. Through their appointment in the Medical Administrative Corps they are placed under military jurisdiction and in an inactive status permitted to complete their medical education to include twelve month internship in approved hospitals. However, it is apparent that unless some provision is made to assure a minimum of two years' premedical education there will be no medical students next year or in succeeding years. Only women and the physically unfit would be able to enter medical school.

I regret that I do not have the details, but I am assured that the War Department is working out plans to provide the necessary future supply of personnel—professional, technical and scientific. I trust that equally comprehensive plans may be developed by the War Manpower Commission for essential industries and civilian communities. It is obvious that the supply of future physicians required both for the military and for the civilian effort must not be curtailed at the source.

DISCUSSION

CHAIRMAN SHOULDERS. One question occurs to the Chair with reference to the matter of quotas for the Army and quotas for physicians. As Dr. Lahey stated, the quota is 1 doctor for 1500 population, whereas the Army has the quota, I believe, of 65 per thousand. Has there been any alteration or any approach to the question with reference to any adjustments that may be necessary?

DR. FRANK H. LAHEY. Admiral McIntire has stated that the Navy will function on 65. Aviation has stated the same. The Army, I am sure, will go along with any reasonable figure. They don't know quite what they are going to have to deal with in the way of casualties, but I believe in this plan we have set up some figures which are workable now.

DR. STANLEY B. WELD, Hartford, Conn. I wish that Surgeon General McIntire might have enlarged a little more on the question of what we are going to do with specialization in the postwar period. I have a letter which was sent to me from one of our sister states in New England that really belongs to Dr. Lahey, and I am going to read it at this time, hoping he may be able to answer these questions.

"Two things bother me a bit, and if at Chicago some one can explain, then I will be appreciative at least.

1. Why is it a man can volunteer for induction into the armed forces, be rejected by an examining board and told he is unfit and to go do something in way of a job, and then have his Selective Board classify him in 1-A and order him up for examination and he is accepted pronto? Are there two grades, one for the Selective Service and one for volunteers?

2. Why was all this talk that the Procurement and Assignment agency would not strip the smaller communities of medical men, or allow it to be done, and then act directly the opposite? Why were the younger men summarily designated as available in many cases without the local Procurement and Assignment member being asked for his opinions? Also thus. Why in some places did Washington go over the heads of the state Procurement and Assignment director and direct a local army officer to turn on the heat to any man under a certain age?

"Some men in the Army Medical Corps from civilian life seem to be imbued with the idea that they should be tough and

simply will not consult with the county Procurement and Assignment representative who should know about the situation. If he doesn't, then he should be summarily fired."

BRIGADIER GENERAL HILLMAN. There is an adequate explanation, I feel, for that first question, as to why men are first rejected and then are later called up and accepted. This is a changing period. My own ideas about physical standards have necessarily been modified according to the demand. It is a little like the ratio of medical officers. We are trying to cut our garment to fit the cloth we have. We have had to reduce our standards, and with successive editions of our Mobilization Regulation 1-9 which sets forth physical standards, the standards have been reduced. For instance, the visual standards have been definitely reduced from what they were originally. You can see that with the reduction of eye standards, the local boards are justified in sending up a great number of men who were rejected originally because of defective vision. A lot of those individuals are accepted. The local boards in many instances were not able to supply a sufficient number of men according to the existing regulations, and the War Department saw a number of men coming into the service below their requirements. The War Department turned on the heat and said, "You have certain standards, but let's just don't be quite so punctilious about those standards. Let's have a little lower threshold of admission into the Army." Selective Service sent back individuals. With that change in atmosphere it permitted them to be accepted when they would not otherwise be accepted.

CHAIRMAN SHOULDERS. Is the physical standard of the Army for a commission above the standard of the draft board?

BRIGADIER GENERAL HILLMAN. At present anybody who is inducted into the service under Selective Service is eligible, as far as his physical condition is concerned, to attend an officers' training school. The Army does not necessarily promise him that he can attend an officers' training school for general service, but it does promise him an opportunity, if he is otherwise qualified, to obtain a commission.

Let me explain for just a moment why we can't have limited service standards for induction, and limited service standards for appointment as an officer, and general service standards for induction and general service standards for appointment as an officer parallel.

Let's go back to the eye situation again. We feel that an individual with vision of 22/100 corrected to 20/20 with glasses, can serve as an enlisted man, but because of the greater responsibility of the officer and the necessity for him to use complicated optical instruments in the direction of artillery fire, in the observation of signals, in the observation of aircraft, we feel he must have a fair standard of vision because of his greater responsibilities and the need, you might say, for his protecting the lives and safety of the organization. So the standards are not exactly parallel. But a man who is inducted in the service will not be debarred physically from getting a commission for limited or general service if he can be kept in the service. If it is found, when he comes up for examination for officers' training camp that he has a condition which precludes his serving as an officer then he would be released from military service and discharged on a certificate of disability.

Our standards as to appointment have materially changed in the last two years as the need for more and more officers in the service has become evident. Individuals were refused commissions over the past year or two years because of not meeting certain physical standards, and they have been given the opportunity to stay in the Reserve Corps if they had fifteen or more years' service in the Reserve. Otherwise they were allowed to resign or be discharged. Some of those individuals have come up before army induction boards, and the army induction boards have not paid much attention to the defects they have shown and which have been the cause for rejection as officers, and they have been inducted. But such individuals who have been inducted can write to the War Department and remind the War Department of their previous status as a reserve officer, and the fact that they were discharged from the Reserve because of a physical defect and get that defect waived.

DR. HOLMAN TAYLOR, Fort Worth, Texas. Do I understand the General to say that a doctor who has been inducted into the service as an enlisted man and has been sent to an officers' training school and found not to meet the physical requirements will be discharged from the service or will he, rather, revert to the status of an enlisted man?

BRIGADIER GENERAL HILLMAN. A graduate physician, if he is kept in the service, will get to serve as a physician and be appointed as a physician.

COL LEONARD G ROWNTREE The standards for acceptance depend on three things. The urgency of the need is first, the size and nature of the pool, and the size and nature of the service you want to fill. As these three are constantly changing so the standards change. In the beginning we had a large group of 1 B men who were kept to one side during the last four months, and by the first of the year that will be completed the whole group has been reexamined, and a large proportion of that group is now in the Army that was not acceptable before. We have perhaps a million and a half men in the 4-F group. This 4-F group will have to be subjected to reexamination and reclassification for the reason given by General Hillman, the changing standards due to the changing urgency of need.

DR WILFRED HATCHER, Battle Creek, Mich. This is a question of examination of inductees before they are sent to the induction center, that is, the men are called up and the local examining board examines them in our localities. If a man has one glass eye we have to send him on. If he has a complete atresia of the ear canal, what are we going to do? We know those fellows won't be accepted by the Army. We are told that in some places in this country—in three states that have been given to us—local examinations are not being made, only the laboratory checkup, and so forth, is made, and that the doctors don't have to put in this time out of their tremendously busy hours in going over such a haphazard method of examination where we ship them on, and we know they can't pass. They pay no attention to it. If we pass them, they go to the induction center.

COLONEL ROWNTREE You were misinformed as to three states proceeding on the basis of no examination. That is not correct. The standards have been set up in conference with the War Department and the Surgeon General's Office and it has been decided what the procedure shall be. The procedure is working out effectively, particularly where the regulations are followed.

DR CREIGHTON BURKER, New Haven, Conn. A physician applies for a commission in good faith, and he is examined by a medical examining unit. He is found disqualified and is told by the Surgeon General he is not eligible for appointment to a commission status. Then the next week or perhaps the next month this man is picked up in the Selective Service, is brought before his local screening examination and they don't throw anybody out if he can struggle up the stairs. He is sent up the

induction line, and the induction line, having a different standard of physical qualifications, will order that man for induction unless by some circumvention of the law we pick that fellow off the induction line. That I believe, is the question that has been propounded, and up to now it hasn't been answered.

COLONEL ROWNTREE It seems to me that General Hillman gave a specific and direct answer to it. Both actions were actions of the induction board. In one instance it was an examination for a place as an officer. The next is the induction board examining that man and he is taken into service. He also went further to say that, if a man is well qualified, he is fished out and either given professional service or, if he cannot qualify, is given his certificate of disability for discharge.

DR A T MCCORMACK, Louisville, Ky. I want to speak of one group that hasn't been mentioned. Many of us represent agricultural states. After all is said and done, we can say what we please about industry and about all the other elements in this total war, but the one group that is essential to the preservation of this country and of civilization is the farmer and the food producers. They are the only people who produce new wealth in this country, and it is absolutely essential that we make provision not only for medical care but for keeping them on the farm. It is not at all important that the problem is all solved. As soon as they find out how good they are, every farmer wants to go to that place because he gets good medical attention, good food and everything else. What are we going to do to take care of the health and lives of farmers of this country? I was in a rural section of Kentucky the other day where, within 50 miles 86 per cent of the women are delivered by midwives because there are no doctors. That is a section of Kentucky where the birth rate is the highest in the United States, and it is contiguous to Tennessee. It has some of their same habits. It is a very important section of the country, because it has produced leaders for this country. It has produced laborers, it has produced bankers and it has produced statesmen. We have twenty-six counties in Kentucky from which no physician has gone to the armed forces. They are in the same fix they were in before the war, they are still short. We have only six that have gone below 2,000 population per physician since war has been declared. That problem still remains and that problem has to be answered and has to be answered by the medical profession.

(To be continued)

THE VICTORY TAX AND THE MEDICAL PROFESSION

PREPARED BY THE
BUREAU OF LEGAL MEDICINE AND LEGISLATION

The Revenue Act of 1942 imposes a victory tax on individuals amounting to 5 per cent of their victory tax net income. This tax is in addition to all other taxes imposed by the new act, applies to income received after Dec 31, 1942, and will continue in effect during the present war. The act provides that the victory tax shall not apply with respect to any tax year commencing after "the date of cessation of hostilities in the present war." Physicians of course will be subject to this tax to the same extent as other taxpayers.

The return that a physician must file on or before March 15, 1943, will not reflect the victory tax net income of the taxpayer nor will the victory tax be payable at that time. Since the new tax applies only to income received after Dec 31, 1942, and since the next return includes only income prior to Jan 1, 1943, assuming that the physician is on a calendar year basis for income tax purposes, physicians generally need not be concerned with the payment of the victory tax until their returns are executed, in 1944, for the tax year 1943. There are certain aspects, however, of the victory tax provisions of the new act that will impose requirements on physicians beginning with the first of the year.

PHYSICIANS WHO ARE EMPLOYERS

If a physician on or after Jan 1, 1943, employs any person, subject to certain exceptions discussed later on, and pays to such a person a wage in excess of \$12

a week, or \$624 a year, he must withhold the 5 per cent victory tax from that wage and transmit it to the government at quarterly intervals.

What Constitutes Wages—Affirmatively, the term "wages" means all remuneration, other than fees paid to a public official, for services performed by an employee for his employer, including the cash value of all remuneration paid in any medium other than cash.

Negatively, the term does not include remuneration paid (1) for services performed as a member of the military or naval forces of the United States, other than pensions and retired pay, (2) for agricultural labor, (3) for domestic service in a private home, local college club or local chapter of a college fraternity or sorority, (4) for casual labor not in the course of the employer's trade or business, (5) for services as an employee of a nonresident alien individual, foreign partnership or foreign corporation, if such individual, partnership or corporation is not engaged in trade or business in the United States, (6) for services as an employee of a foreign government or any wholly owned instrumentality thereof, and (7) for services performed as an employee while outside the United States, unless the major part of the services performed during the calendar year by such employee for his employer are performed within the United States. Persons who perform services in the foregoing seven categories are

not exempt from the payment of the victory tax, but their employers are not required to withhold the tax from their wages

The definition of the term "wage," therefore, is broad enough to include the remuneration paid by a physician to an assistant physician, an office nurse, a stenographer, a secretary, a receptionist and other personnel employed by the physician in connection with his practice

Withholding Deductions—Not all of an employee's wage is subject to the victory tax, only that in excess of \$624 a year. In computing the 5 per cent victory tax to be withheld, therefore, the employer will disregard the wages paid for each payroll period in accordance with the following schedule

Payroll period	Withholding Deduction
Weekly	\$ 12
Biweekly	24
Semimonthly	26
Monthly	52
Quarterly	156
Semiannually	312
Annually	624

That is, if the payroll period for a particular employee is a week, the tax does not apply to the first \$12 paid the employee, if the payroll period is a month, the first \$52 escapes the victory tax, and so on. All wages paid in excess of the indicated amounts for each payroll period are subject to the tax and employers must either withhold 5 per cent of that excess or an amount in accordance with tables set forth in the act. These tables indicate optional amounts an employer may withhold instead of the actual 5 per cent of the wage. As an example, for a weekly payroll period, if the wage paid is over \$12 and not over \$16, 10 cents weekly may be withheld. If the wage is over \$20 but not over \$24, 50 cents may be withheld and so on for different wage groups for different payroll periods. The use of these tables will simplify greatly the withholding process and physicians should ascertain from the office of the collectors of internal revenue where copies of the table may be obtained.

The law provides that, if a payroll period is less than one week, the excess of the aggregate of the wages paid during each calendar week over the deduction allowed for a weekly payroll period must be used in computing the tax required to be withheld. For example, if an employee is paid on a daily basis at the rate of \$5 a day, the employer will not withhold any of the wage paid for the first two days of employment in any calendar week. The wages paid for a third day in the same calendar week will be subject to withholding on \$3, the excess of the aggregate of three days' wages, or \$15, over the weekly deduction of \$12. All subsequent wage payments during the same calendar week will be subject to withholding on the entire amount of each payment. If a payroll period is not covered specifically by the foregoing table, the deduction allowed against each payment of such wages will be the deduction allowable in case of an annual payroll period divided by 365 and multiplied by the number of days in such period, including Sundays and holidays.

In any case in which wages are paid by an employer without regard to any payroll period or other period, the deduction allowable against each payment of such wages will be the deduction allowable in the case of an annual payroll period divided by 365 days and multiplied by the number of days, including Sundays and holidays, which have elapsed since the date of the

last payment of such wages by such employer during the calendar year, or the date of commencement of employment with such employer during such year or January 1 of such year, whichever is the later.

In withholding the victory tax, the employer gives no consideration at all to the marital status of the employee or to any dependents that the employee may have, or to any possible deductions to which the employee may be entitled, other than the basic deduction of \$12 a week.

Transmission of Withheld Tax to Government—The employer who has withheld the victory tax from wages paid to employees is required to transmit the withheld tax to the government on or before the last day of the month following the close of each quarter of each calendar year. The first report to be made by an employer to the government, therefore, will be due on or before April 30, 1943. Such an employer must keep such records and render under oath such statements with respect to the tax withheld and collected as may be required under regulations prescribed by the Commissioner of Internal Revenue with the approval of the Secretary of the Treasury.

Receipts to Employees—Every employer withholding the victory tax must furnish to each employee, on or before January 31 of the succeeding year, or, if the employment is terminated before the close of the calendar year, on the day on which the last payment of wages is made, a written statement showing the period covered by the statement, the wages paid by the employer to such employee during such period, and the amount of the tax withheld and collected. Duplicate copies of such statements must be transmitted to the Commissioner of Internal Revenue along with the final report made by the employer for the calendar year.

PHYSICIANS WHO ARE EMPLOYEES

A physician who is an employee may expect deductions to be made from his wages in accordance with the procedure outlined. The deductions will be made by the employer, subject to the exceptions previously noted, whether that employer is the federal or a state government, a county, a municipality, an agency or instrumentality thereof, a hospital, an industrial or business concern or other person or agency paying wages to a physician. While physicians generally will not be required to pay the victory tax until 1944, and then on income received during 1943, physicians who fall in the category of employees will start paying the tax periodically in 1943 as it is deducted from their wages by their employers.

At the end of the tax year 1943 the victory tax that has been withheld from the wages of a physician employee will be adjusted. This adjustment will take place when the return for 1943 is filed the early part of 1944. At that time the victory tax will be redetermined on the return then filed and credit taken for the amounts that have been withheld from wages. Since the amounts so withheld are based on 5 per cent of the gross income in excess of \$624 a year and since the actual victory tax imposed is 5 per cent of the victory tax net income, that is, gross income minus specified deductions in addition to the \$624, there will in many instances be an excess in the amount withheld over the tax actually due. In such case that excess may be deducted from the income tax that will be payable. In all cases, therefore, in which employers have withheld, during 1943, periodic amounts from wages on account of the victory tax, there will be

adjustments between the government and the taxpayer at the close of the tax year if such adjustments are necessary

POSTWAR CREDIT OR REFUND OF VICTORY TAX

As soon as practicable after the date of cessation of hostilities in the present war the following amounts of victory tax paid for each taxable year beginning after Dec 31, 1942 will be credited against any income tax or installment thereof then due from the taxpayer and any balance will be refunded immediately to the taxpayer

1 In the case of a single person or married person not living with husband or wife, 25 per cent of the victory tax or \$500, whichever is the lesser

2 In the case of the head of a family, 40 per cent of the victory tax or \$1,000, whichever is the lesser In the case of a married person living with husband or wife where separate returns are filed by each spouse, 40 per cent of the victory tax or \$500, whichever is the lesser In the case of a married person living with husband or wife where a separate return is filed by one spouse and no return is filed by the other spouse, or in case of a husband and wife filing a joint return only one such credit will be allowed and such credit may not exceed 40 per cent of the victory tax or \$1,000, whichever is the lesser

3 For each dependent, excluding as a dependent in the case of the head of a family, one who would be excluded as a dependent for income tax purposes, 2 per cent or \$100, whichever is the lesser

If for any taxable year the status of the taxpayer, other than a taxpayer whose gross income is \$3,000 or under and who uses the simplified return form, with respect to his marital relationship or with respect to his dependents, changes during the taxable year, the amount of the credit or refund of the victory tax for such taxable year will be apportioned, under rules and regulations prescribed by the Commissioner of Internal Revenue with the approval of the Secretary of the Treasury in accordance with the months to and after the change For the purpose of such apportionment, the fractional part of a month will be disregarded unless it amounts to more than one-half a month, in which case it will be considered as a month

The law contains provisions under which a taxpayer may, prior to the cessation of hostilities, take advantage of his postwar credit or refund To the extent of that credit or refund, the taxpayer may reduce the victory tax by deducting amounts paid during the year as premiums on life insurance in force on Sept 1, 1942, certain reductions of debts and certain investments in obligations of the United States At the end of 1943 and of each year thereafter in which the victory tax is imposed the taxpayer may, with respect to that tax, do one of two things (1) He may pay the victory tax in full and wait until the cessation of hostilities to claim his postwar refund or credit, or (2) he may at the time the victory tax is payable reduce the amount of the tax by deducting expenditures for purposes above described in an amount equal to the postwar refund or credit to which he would be entitled after the cessation of hostilities Assume that Dr X, an unmarried physician with no dependents, when he executes his return on or before March 15, 1944, finds himself owing a victory tax of \$100 Assume, further, that during 1943 Dr X purchased government bonds, paid premiums on life insurance and reduced indebtedness, expending a total amount of \$1,000 for such purposes Dr X may pay the \$100 victory tax during 1944 and after the cessation of hostilities receive a refund or credit of 25 per cent of the tax, or \$25, or he may reduce the victory tax payable in 1944 by claiming credit for the amount expended for the purposes stated but only to the extent of the postwar credit to which he would be entitled, that is, \$25 In the one case, Dr X pays the full victory tax of \$100 and gets a refund or credit later, in the other he pays \$75 and will not thereafter receive a refund or credit

No attempt has been made to discuss in detail the intricacies of the victory tax The object has been rather to present a broad picture with many of the technical details omitted As previously stated, the tax does not extend to 1942 incomes and physicians generally will not have to compute the amount of the tax they must pay until the returns are filed on or before March 15, 1944 Before that time arrives, it is assumed that proper regulations will be promulgated and be given wide publicity which will simplify the procedure for the determination of the tax

FIFTH ANNUAL CONGRESS ON INDUSTRIAL HEALTH

The fifth Annual Congress on Industrial Health, sponsored by the Council on Industrial Health of the American Medical Association, will be held Monday, Tuesday and Wednesday, Jan 11-13, 1943, at the Palmer House in Chicago These meetings are open to physicians and others interested in industrial health There is no registration fee The preliminary program is as follows

MONDAY, JANUARY 11—OPENING SESSION, 9 45 A M

Report of the Council on Industrial Health

STANLEY J SEEGER M D Chairman Texarkana Texas

The Physician and Industrial Mobilization

Speaker to be announced

Preventive Medicine in Industry

JOHN H FOULGER M D Wilmington Delaware

Director Haskell Laboratory of Industrial Toxicology

Employee Management Cooperation for Industrial Health

WENDELL LUND Washington D C

Director Labor Production Division War Production Board

Procurement and Training of Professional Personnel for Industrial Health Service

CLARENCE D SELBY M D Detroit

Chairman Subcommittee on Industrial Health and Medicine Federal Security Agency

RED LACQUER ROOM

MONDAY—AFTERNOON SESSION, 2 O'CLOCK

Ocular Signs of Industrial Poisoning

ROY S BOYSTER New York

Chief Safety Inspector Standard Oil Company (New Jersey)

COMMON INFECTIONS IN INDUSTRY

(Joint Presentation by the Council on Pharmacy and Chemistry and the Council on Industrial Health American Medical Association)

Newer Concepts in the Prevention and Treatment of Wound Infections

AUSTIN E SMITH M D Chicago

Secretary Council on Pharmacy and Chemistry

Recognition, Prevention and Essential Treatment of Occupational Dermatitis with Particular Reference to Oil Dermatitis and Folliculitis

Report of Committee on Occupational Dermatoses American Medical Association

Respiratory Infections in Industry. Joint Report Prepared by the Council on Pharmacy and Chemistry and the Council on Industrial Health American Medical Association

CHESTER S KEEFER M D Boston

Wade Professor of Medicine Boston University School of Medicine

Program of Immunization for Industrial Workers

ARKANSAS

Norman Baker Denied Supreme Court Review—Norman Baker, Clark Springs, serving a four year sentence in the federal penitentiary at Leavenworth, Kan., failed to obtain a supreme court review of his contention that he had been denied a fair trial, according to the *Davenport Times*, November 16. He sought a review of a decision by the tenth federal circuit court, which denied him a writ of *habeas corpus* it was stated. Baker was convicted in the federal district court at Little Rock on a charge of using the mail to defraud in connection with alleged claims for the cure of cancer.

CONNECTICUT

Personal—Dr. John C. White, New Britain, has been appointed superintendent of the New Britain General Hospital, succeeding Mr. James S. North, resigned.—Dr. John F. Kilgus Jr., Litchfield, has been appointed medical examiner for the towns of Litchfield and Morris, succeeding Dr. Harry B. Hanchett, Torrington who has been acting medical examiner since the death of Dr. Robert A. Macey, Litchfield.—Dr. Leonard Parente, Hartford, was appointed medical director and adviser for the Connecticut State Department of Public Welfare effective September 1. He will organize and administer the state medical care program for the department.

Hospitals Adopt "Rationing" Program for Maternity Service—St. Vincent's and Bridgeport hospitals, Bridgeport, have adopted a new program to reduce the average hospitalization of maternity patients to seven days after delivery of the baby. At the discretion of the physician, mothers will be hospitalized longer. The new regulation is part of a code which has been adopted, in cooperation with the state medical society and the state board of health, to lessen the demands on hospital personnel. Patients will be asked to cooperate by lessening the number of demands on the time of nurses in instances in which the service has no bearing on the safety of the patient. Suggestions toward that end and other objectives of the new code have been prepared by the public health committee of the state medical society. Visiting hours for all patients will be from 7 to 8 p. m., religious ceremonies will be arranged for at home after discharge from the hospital, and in the event that the ceremony must take place in the hospital, witnesses will be limited to 3 persons. A father will be shown his baby once before the child is prepared for leaving the hospital. Flowers will be received only in special containers which require no time for nurses for arrangement, watering and other attention. Bridgeport florists have agreed to cooperate by supplying chemically treated paper containers in which flowers are already arranged and to which only water need be added. The saving of time of nurses, otherwise occupied with nonessential duties, will be employed to augment the night nursing service.

DISTRICT OF COLUMBIA

New Professor of Surgery—Dr. Fred R. Sanderson, associate professor of surgery at Georgetown University School of Medicine, has been appointed professor of surgery and director of the department and chief surgeon of Georgetown University Hospital, succeeding the late Dr. James A. Cahill. Dr. Sanderson who has been a member of the faculty since 1923 graduated at Georgetown in 1915.

Society News—The Medical Society of the District of Columbia devoted its meeting, November 18, to a panel discussion on undulant fever, brucellosis and Bang's disease. The speakers were Lieut. Col. Arthur Parker Hitchens, M. C., U. S. Army, Philadelphia, and Brig. Gen. Raymond A. Kelsey, M. C., U. S. Army, Washington, D. C.—Dr. Ella Oppenheimer was elected president of the District Society for the Prevention of Blindness at its annual meeting recently and Dr. William S. Anderson was named corresponding secretary of the society. Dr. William Thornwall Davis discussed "The Place of the Community Organization for the Prevention of Blindness in Time of War."

INDIANA

Physician Pardoned—Dr. Paul B. Arbogast, Vincennes, who has served one year of a sentence of from two to fourteen years for presenting false claims against the Vincennes township poor fund, on November 12 received a parole discharge and pardon from the state clemency commission. The *Princeton Democrat* November 12 reported that the commission had received requests from numerous Knox County citizens for the release of the physician so that he could return to his profession. The pardon terms make Dr. Arbogast eligible for immediate restoration of his license to practice medicine, the application of which is to be acted on by the state board of registration.

MASSACHUSETTS

Silver Cup Awarded to State Hospitals—The American Hospital Association during its recent meeting in St. Louis, awarded to the Massachusetts Hospital Association and to the Blue Cross a silver cup in recognition of the best statewide observance of National Hospital Day, May 12. Dr. Charles F. Wilensky, Boston, president of the Massachusetts Hospital Association, accepted the cup in behalf of the hospitals that participated in the observance. The cup will remain the permanent property of the hospital association and the Blue Cross.

Administrative Committee for School of Dental Medicine—An administrative committee has been appointed for the Harvard School of Dental Medicine to carry out general administrative responsibilities. A. LeRoy Johnson, D.D.S., New York, who has just been appointed professor of clinical dentistry in the new school, has been named executive officer of the committee. Other members are Percy R. Howe, D.D.S., Thomas Alexander Forsyth, professor of dental science, emeritus, Kurt H. Thoma, D.M.D., professor of oral surgery and Charles A. Brackett, professor of oral pathology and Dr. C. Sidney Burwell, dean of the medical school, chairman.

Tract of Land Given to Tufts College—Tufts College announces the gift of a tract of land in downtown Boston from Mr. A. Shapiro, Brookline. The property, consisting of five buildings on Tyler Street, was formerly owned by Denison House and adjoins property on Harrison Avenue recently purchased by the college. It is adjacent to the hospitals and dispensaries of the New England Medical Center, of which the Tufts College Medical School is the teaching base. The land was purchased, according to Mr. Shapiro, so that there will be 'plenty of elbow room' around the proposed three quarter million dollar medical building. Leonard Carmichael, LL.D., president of Tufts College, stated that the gift was prompted by the donor's appreciation of the rural medical extension program being developed by the Tufts faculty at the New England Medical Center, a project whereby many local communities in Maine were benefiting from the school's extension of laboratory and diagnostic services, training of local hospital technicians and assistance in organizing emergency medical protection, such as a statewide network of civilian blood banks. President Carmichael also announced according to the *New England Journal of Medicine* that more than \$500,000 has now been subscribed for the new building for the medical school, and efforts are being made to complete the fund so that construction may start as soon as conditions permit.

MICHIGAN

Personal—St. Mary's Hospital, Detroit, held a dinner November 7, at the Hotel Statler to honor Dr. William A. Repp, Detroit, on his completion of fifty years in the practice of medicine and as a member of the staff of the hospital.—Dr. Marie A. Hagele, Lansing, upper peninsula regional consultant in maternal and child health for the state department of health since 1939, has resigned to join the staff of the Sault Ste. Marie polyclinic. Dr. Hagele had also been acting director of the Alger-Schoolcraft Health Department for the last month.

Cooperative Study of Mouth Conditions in Escanaba—The U. S. Public Health Service, the University of Michigan and the state health department are cooperating in a study of mouth conditions of children in Escanaba, seeking particularly to measure discovered amounts of acid forming bacteria which cause decay. According to *Public Health News*, the study now being carried on in Escanaba has been undertaken because the projected use of fluorine-bearing water by that city in the future will afford a basis of comparison with mouth conditions found there now. Escanaba now obtains its water supply from Bay de Noc but to obtain more satisfactory supplies wells have been driven which produce water containing 0.5 per million part of fluorine. The new supply cannot be turned into mains until the war ends because it is impossible to obtain necessary pumping equipment. *Public Health News*.

stated that there is reason to believe that the quantity of fluorine present in the water obtained from the Escanaba wells is adequate to lessen tooth decay without causing mottling. It is known that 1 part per million of fluorine will cause such mottling in some instances.

MINNESOTA

Physician's Portrait Given to Hospital—A portrait of Dr. Walter H. Valentine, Tracy, was presented to the Tracy Hospital by Dr. Herman F. McChesney, Brooklyn, a cousin and classmate of Dr. Valentine at Carleton College, Northfield, in the nineties, according to *Minnesota Medicine*. Dr. Valentine graduated at the University of Minnesota Medical School, Minneapolis, in 1900 and started in practice the same year in Tracy. The gift was made to mark Dr. Valentine's many contributions of service to the community. The portrait is the work of Walter Scott Darr, New York.

Kenny Poliomyelitis Institute—The Public Health Center, formerly known as the Lymanhurst Health Center, Minneapolis, has now been officially designated the Elizabeth Kenny Poliomyelitis Institute. Miss Kenny's clinic is established there and will operate under its present financial setup until January 1, when the Minneapolis Welfare Board will set up a board of trustees to supervise finances after that time, according to *Minnesota Medicine*. The city heart clinic now being operated in the same building will continue there, but its budget will be kept separate from that of the poliomyelitis institute, it was stated.

Hospital News—Dr. Magnus C. Petersen has resigned as medical superintendent of the Willmar State Hospital, Willmar, to accept a similar position at the Rochester State Hospital, Rochester, succeeding Dr. Benjamin F. Smith, who became superintendent of the St. Joseph's Hospital, St. Joseph, Mo. Dr. George H. Freeman, medical superintendent of the St. Peter State Hospital, St. Peter, is acting superintendent at the Willmar institution pending the appointment of a successor to Dr. Petersen. Dr. Francis E. Harrington has been appointed director of the Minneapolis General Hospital during the absence of Dr. Donald W. Pollard, who is in active service.

Grant to Establish Professorship in Cancer Research—The Citizens Aid Society of Minneapolis has given \$5,500 a year for five years to the University of Minnesota. Minneapolis to support what will be known as the George Chase Christian professorship in cancer research. It will be the first professorial chair in the medical school to be named for an individual. The first incumbent to the new position will be John J. Bittner, Ph.D., associate director and vice president of the board of directors of the Roscoe B. Jackson Memorial Laboratory, Bar Harbor, Maine. Working with Dr. Bittner will be Drs. Maurice B. Visscher, professor of physiology and head of the department and Robert G. Green, professor of bacteriology and immunology, who are studying the etiology of mammary cancer in mice. Dr. Bittner will approach the cancer problem as a geneticist. Dr. Visscher as a physiologist and Dr. Green as a bacteriologist with a special interest in viruses. Three factors in the etiology of mouse cancer on which the three men have been working are that cancer is transferred by an agent in mother's milk that mammary gland development is stimulated by estrogenic substance and the likelihood that a virus agent is present in advance of the cancer development. Dr. Bittner will move to Minneapolis as soon as housing and laboratory arrangements can be made. He was born in Meadville, Pa., in 1904, graduated at St. Stephens College in 1925 and became a research assistant at the University of Michigan, Ann Arbor, in 1927, receiving his Ph.D. there in 1930. He delivered the George Chase Christian lecture at the University of Minnesota in 1940. The Cancer Institute in the University Hospital is a memorial to the late Mr. Christian, and Mrs. Christian, a resident of Minneapolis, has encouraged the Citizens Aid Society in support of cancer research for many years.

MISSOURI

Barnard Hospital Lecture—Dr. Francis Peyton Rous of the Rockefeller Institute for Medical Research, New York, delivered the fourth annual Barnard Free Skin and Cancer Hospital Lecture before the St. Louis Medical Society, November 17 on "The Nearer Causes of Cancer."

Cornerstone Laid for New Health Center—The cornerstone of the new brick health center for St. Louis County was laid with appropriate ceremonies in Clayton on October 27. The structure, which is expected to be completed in April, is being erected with the assistance of federal funds and will cost more than \$500,000. When completed, it will serve as a national

training center for public health student physicians and nurses. It will also replace the temporary inadequate headquarters of the county health department and relieve overcrowding at the St. Louis County Hospital, adding eighty beds to the present two hundred bed capacity, according to the *St. Louis Post Dispatch*. The center will be a five story building with a three story wing. All of the department's clinics will be housed on the first floor. The second and third floors will be used for administrative offices, class rooms and lecture halls. On the fourth floor will be a forty bed pediatric isolation ward and on the fifth a forty bed ward for adults with ailments which present special problems for study.

NEBRASKA

New State Health Officer—Dr. Claude A. Selby, North Platte, formerly president of the Nebraska State Medical Association, has been appointed director of health of the Nebraska State Health Department.

NEW HAMPSHIRE

Health Plan Expanded at New Hampshire University—A war program of physical fitness for women patterned after the physical training given the WAVCs and WAVEs was started at the University of New Hampshire, Durham, November 30 according to the *New York Times*. The basic war program would include conditioning and rhythmic, with a supplementary program of individual gymnastics, skating, basketball and community games.

Dr. Edward Colby Appointed Acting Director of Epidemiology Division—Dr. Edward W. Colby, Exeter, health officer of the Eastern Health District of the state board of health, has been appointed acting director of the division of epidemiology and venereal disease control of the state department at Concord. Dr. Colby will continue as health officer of the Eastern Health District until a new health officer has been appointed. *THE JOURNAL*, November 14, page 852 attributed this appointment to Dr. Elton W. Colby, who is in private practice at Exeter.

NEW JERSEY

Squibb Biologic Laboratories Expanded—Completion of the important new additions to the biologic laboratories of E. R. Squibb and Sons, New Brunswick, are being translated into enlarged production of serums and vaccines to assist in the war effort, it is announced. The latest building expansion move includes a three story extension to the main laboratory building and two new one story individual laboratory structures. A portion of the new main laboratory addition will be devoted to the preparation of human serum albumin developed under the direction of Edwin J. Cohn, Ph.D., professor of biochemistry at Harvard Medical School, Boston, which is to be used in the armed forces for the prevention and treatment of shock. (*THE JOURNAL*, November 28, p. 1041). Two smaller one story buildings will be devoted respectively to the manufacture of typhus vaccine and smallpox vaccine.

NEW YORK

Fighters in White—A Movie—The state department of health has recently released a sound motion picture entitled "Fighters in White." Describing the organization and operation of the emergency medical service, the picture is now being booked in motion picture theaters throughout the state.

Personal—A commemorative medal in honor of the late Dr. Aaron L. Higgins at one time president of the Nassau County Medical Society and for twenty years physician for the St. Agnes Knights of Columbus council in Rockville Center, will be awarded annually by the council to a pupil in St. Agnes Grammar School, it is reported. Dr. Higgins died on July 17.

Society News—The Buffalo Academy of Medicine will be addressed, December 9 by Drs. Clyde L. Randall on "Vaginal Discharges," Louis A. Siegel, "Endocrines in Obstetrics and Gynecology," and Edward G. Winkler "Forceps Delivery." All are from Buffalo.—Dr. Winthrop M. Phelps, Baltimore, lectured at the Children's Hospital of Buffalo, December 2, on "Treatment of Cerebral Palsies." The lecture was given in connection with the observance of the fiftieth anniversary of the hospital.

New York City

Clinics for Antirabies Injections Closed—The Bronx and Queens clinics for the treatment of persons needing antirabies injections were to be closed November 2, because of "the general need of physicians and the fact that the number

of patients at the antirabies clinic fluctuates," according to the *Brown Home News*. Persons requiring such treatment in Queens will have to go to the Brooklyn Clinic, it was stated.

Physicians' Hobby Show—An art exhibit and hobby show, sponsored in cooperation with Elmer and Amend, opened November 17 at the Apothecary to continue until December 18. The display includes etchings, paintings, sculpture and photography of physicians in the metropolitan area. Included in the exhibit are etchings which have been donated by the members of the Hudson Fishing Club, a group of physicians and dentists. The proceeds of the sales of these etchings will be turned over to the American Flying Services Foundation which is giving medical services to correct the minor physical defects that bar American youth from acceptance by the army and navy air service.

Medical-Dental Meeting—The twelfth annual combined medical dental meeting of the organized medical and dental professions of Greater New York will be held at the Hotel Pennsylvania on December 7. Participants will include James E. Aigner D.D.S., Philadelphia, on 'Pain Control Before, During and After Dental Procedures', Dr. Harold F. Hyman, 'Interrelationships Between Medical and Dental Practices', Commander Lloyd R. Newhouser, M.C.U.S. Navy, 'Treatment of Shock, Including Use of Blood Plasma' and William J. Gies Ph.D., 'Resumen of Research on Dental Caries'. Representatives of the army and navy dental corps will discuss "War Injuries."

Changes in Faculty at New York University—Included among recent appointments to New York University College of Medicine are the following:

Drs. Walter Cuernsey Gray Jr. and Frank C. Keil to assistant clinical professors of ophthalmology,
Chester W. Humpal Ph.D. to visiting professor of physiology
Dr. Theodore Roventhal to assistant professor of preventive medicine
Drs. John Dennis Cooney and Herbert M. Ill to associate clinical professors of urology
Mark H. Adams to assistant professor of bacteriology

The following promotions were also announced:

Dr. Joseph Pick to professor of anatomy
Dr. Timothy J. Riordan to associate clinical professor of dermatology and syphilology
Drs. Maurice J. Costello and William Director to assistant clinical professors of dermatology and syphilology
Dr. James A. Shannon to associate professor of medicine
Dr. Robert S. Goodliart (on leave of absence for government service) to assistant professor of medicine
Dr. Charles E. Kossmann (on leave of absence for military service) to assistant professor of medicine
Dr. Harry Most to assistant professor of clinical pathology
Dr. Joseph J. Bunini to assistant professor of clinical medicine
Dr. Morris B. Bender to assistant professor of neurology
Dr. Conrad Berens to professor of ophthalmology
Dr. John C. McCauley Jr. to associate professor of clinical orthopedic surgery
Dr. William A. Walker to associate clinical professor of orthopedic surgery
Dr. Ernst W. Bergmann to assistant clinical professor of orthopedic surgery
Drs. David H. Goldstein and Harry Most to assistant professors of preventive medicine
Dr. Morris Herman to assistant professor of psychiatry
Dr. Charles Gottlieb to professor of clinical radiology and acting head of the department of radiology
Dr. Harry A. D. O'Connor (on leave of absence for military service) to assistant professor of clinical surgery

PENNSYLVANIA

Society News—Dr. Howard K. Petry, Harrisburg, discussed "Shock Treatment of Psychoses" before the Dauphin County Medical Society in Harrisburg, November 3.—Dr. Robert W. Staley, Pittsburgh, addressed the Huntingdon County Medical Society in Huntingdon recently on "Shock Therapy in Mental Disorders".—The Berks County Medical Society was addressed in Reading, November 10 by Dr. Herbert T. Kelly, Philadelphia, on "Medical Aspects of Nutrition."

Philadelphia

The Mutter Lecture—Dr. Hiram Winnett Orr, Lincoln, Neb., delivered the fifty-fifth Thomas Dent Mutter Lecture before the College of Physicians of Philadelphia and the Philadelphia County Medical Society December 2. His subject was "Physiologic Protection from Infection in Wounds and Compound Fractures."

Outbreak of Ringworm—Thirty children have been sent home from one school because of an outbreak of ringworm. The Philadelphia *Inquirer* reported on November 1. It was stated that the disease was appearing in other city schools. Dr. Hubley R. Owen, city director of public health, asked the cooperation of parents in controlling the disease. School physicians and nurses will notify parents if a child is found to have been infected, and parents were asked to consult the family physician or visit a hospital skin clinic at once.

Graduate Course in Industrial Medicine and Hygiene—A postgraduate course of industrial medicine and hygiene will open at the Philadelphia County Medical Society, January 5, under the auspices of the committees on industrial health of the society and the state medical society and directed by the departments of preventive medicine and public health of the University of Pennsylvania School of Medicine and the Woman's Medical College of Pennsylvania. Eight weeks will be devoted to the course which will be concluded on February 27. A wide range of subjects will be covered, including a consideration of general problems the worker and the job, learning the scope of the field, physical factors affecting health, extreme of air pressures, general safety measures in accident prevention, nonoccupational and allied disease hazards in industry, tuberculosis in industry, toxicology, some of the more complex or hazardous industries, the specialties in industries, changes in industry due to war, presenting special hazards, compensation and medicolegal factors and orientation of medical efforts for health supervision in the future.

TENNESSEE

Health Department Moves—The Memphis and Shelby County Health Department recently moved into a four story remodeled building which once was the home of the University of Tennessee School of Pharmacy. The building is 35 years old and was named Lindsley Hall in honor of Dr. John Berrien Lindsley, the organizer and first dean of the Medical Department of the University of Nashville. Till 1929 it was the main building of the school of pharmacy and until taken over by the health department, was used as one of the buildings of the outpatient department of the University of Tennessee College of Medicine, Memphis. The outpatient department is now housed in the new psychiatric building on Madison Avenue named Gaylor Hall. All units of the county health department are now located in the building, but offices of the health commissioner will be retained in the old quarters at the courthouse.

TEXAS

Activities at University of Texas—The faculty of the University of Texas Medical Branch Galveston has agreed to discontinue the department of legal and cultural medicine established in 1940 in the effort to administer as a single unit the library, social service, medical illustration and hospital record room. The library has been restored to independent status, and social service, medical illustration and hospital records were placed under the hospital administration. The faculty also abolished the stenographic and technical bureaus and restored secretaries and technicians to various departments as needed. Dr. Carl A. Nau, formerly director of the industrial hygiene division of the state department of health, Austin, has been appointed professor of preventive medicine and public health at the university.

VIRGINIA

Personal—Dr. M. Pierce Rucker has succeeded Dr. Wyndham B. Blanton as editor of the *Virginia Medical Monthly*, both of Richmond.—Carl C. Speidel Ph.D., professor of anatomy at the University of Virginia, Charlottesville, received the honorary degree of doctor of science October 23, at the Founders Day exercises of Lafayette College.

Special Society Elections—Dr. John S. Weitzel, Richmond, was named president of the Virginia Pediatric Society at its recent meeting in Roanoke and Dr. Edwin A. Harper, Lynchburg, vice president. Dr. Emily Gardner, Richmond, is the secretary-treasurer.—At a meeting of the Virginia Radiological Society in Roanoke, October 6, the following officers were reelected: Drs. Wright Clarkson, Petersburg, president; Clayton W. Eley, Norfolk, vice president; and Charles H. Peterson, Roanoke, secretary-treasurer.—Dr. Bryant E. Harrell, Norfolk, was elected president of the Virginia Urological Society at its meeting in Roanoke October 6. Dr. Thomas B. Washington, Richmond, vice president and Dr. Warren W. Kooztz, Lynchburg, reelected secretary.

WASHINGTON

Head of Industrial Unit—Dr. Lloyd M. Farner, Nashville, Tenn., U.S. Public Health Service, has been placed in charge of the new industrial hygiene division of the state department of health. Dr. Farner, who has been lent to the state by the public health service, organized and served as director of a similar division in Montana and later as director of industrial hygiene in Tennessee.

WEST VIRGINIA

Personal—Dr Guy Hinsdale, who for thirteen years served as medical director of the Greenbrier Hotel and Cottages, White Sulphur Springs, has moved to Lewisburg. The former "spa" has been taken over by the government to be converted into an army hospital.—Dr Lenore V L Patrick, Chippewa Falls Wis., formerly with the Wisconsin State Board of Health has been appointed chief of the bureau of maternal and child health of the West Virginia Department of Health. It is reported.

WISCONSIN

Forum on Intestinal Tract—The Medical Society of Milwaukee County sponsored three lectures on the gastrointestinal tract, November 2-4, in the form of an open forum. Functional disorders were discussed by Drs Walter C Alvarez, Rochester, Minn. Walter A Brussock, Frederick W Madison and Roland A Jefferson all of Milwaukee, neoplasms by Drs William A O'Brien Minneapolis John Edvin Habbe and Joseph M King both of Milwaukee, and inflammatory disorders by Drs Rudolf Schindler, Chicago, William M Jermain Gervase S Flaherty and Silvanus A Morton, all of Milwaukee.

Helmholz Lecture—Dr Harry Goldblatt, professor of experimental pathology, Western Reserve University School of Medicine, Cleveland, delivered the annual A C Helmholz Lecture before the University of Wisconsin Medical Society, November 5, on 'Experimental Observations on Hypertension'. The Helmholz Lecture is financed by funds which were left to the university for the purpose by the children of Mr and Mrs August C Helmholz who were long residents of Milwaukee. Dr Henry F Helmholz Rochester Minn., one of the children, graduated at Wisconsin and received his degree at Johns Hopkins University School of Medicine, Baltimore, 1906.

GENERAL

College of Physicians Cancels 1943 Meeting—The board of regents of the American College of Physicians has announced the cancellation of the 1943 annual session, which was scheduled to be held in Philadelphia, April 13-16.

National Board Examinations—In order to fit the examinations of the National Board of Medical Examiners to the accelerated programs in the medical schools the board has decided to hold two examinations this winter. The first will be held January 20-22 and the second March 1-3.

Board of Pediatrics Abolishes Group I—The American Board of Pediatrics Inc. announces that Group I, physicians who have specialized in pediatrics for ten years or more will be abolished on July 1. The board wishes to give all physicians who may fall into this group ample warning that the final date for filing applications under this group is nearly up.

Casselberry Awards—A sum of money is now available from the Casselberry Fund of the American Laryngological Association for a prize award, decoration or grant to be given for original investigation in the art and science of laryngology or rhinology. These must be in the hands of the secretary, Dr Arthur W Proetz 1010 Beaumont Medical Building, St Louis before March 1.

Southeastern Surgical Assembly Discontinued—The assemblies of the Southeastern Surgical Congress have been discontinued for the duration of the war or until such time as the executive council decides to continue them again, according to an announcement from Dr Benjamin T Beasley, Atlanta Ga., secretary-treasurer. The publication of the *Southern Surgeon* has also been discontinued for the same period of time or for such time as the executive council considers it advisable to resume publication.

Accidents Compared to War Casualties—According to the National Safety Council, casualties to the U S armed forces from Pearl Harbor to November 15 excluding the African campaign, have been 5,694 dead, 3,435 wounded and 39,827 missing or prisoners, a total of 48,956. These figures are from the government. Casualties to American workers through accidents in the same period have been 44,500 dead and 3,800,000 wounded. These figures are from the National Safety Council. The total American accident toll since Pearl Harbor has been 89,000 killed and approximately 8,800,000 wounded, including thousands of skilled workers.

Northwest Regional Conference Revived—A meeting was held in St Paul, November 8, which served as a revival of the old Northwest Regional Conference. Representatives of Wisconsin, Iowa, North and South Dakota and Minnesota attended the session and elected Dr Raymond G Arveson, Frederic, Wis., as president and Mr R R Rosell, St Paul, executive secretary of the Minnesota State Medical Association as secretary. It was decided to change the name to the

North Central Medical Conference from the Northwest Regional Conference and to hold the next meeting in St Paul. The local conference was revived for the purpose of discussing problems affecting the neighboring states which made up the old Northwest Regional Conference. According to Mr Rosell, the revival of the conference will not in any way affect the National Conference on Medical Service which was an outgrowth of the old Northwest conference. No formal papers were presented at the recent meeting. Discussions, which were of the round table type and informal, centered on rationing, medical licensure law enforcement, medical service plans and state and national legislation.

The Charles L Mayer Awards Created—The National Science Fund announces the creation of two \$2,000 prizes to be known as the Charles L Mayer awards and to be presented in 1942 and 1943 for outstanding contributions to our knowledge of factors affecting the growth of animal cells with particular reference to human cancer. One prize will be awarded for a contribution published in 1942 or submitted to the National Science Fund. A similar prize will be awarded in 1943. A special advisory committee has been appointed consisting of Robert R Williams DSc discoverer of vitamin B₁₂ and chemical director of the Bull Telephone Laboratories, New York. Dr Alan Gregg director for the medical sciences of the Rockefeller Foundation, New York, Dr George H Whipple dean of the School of Medicine and Dentistry of the University of Rochester, Rochester N Y, and Elihu Root Jr, LL.D. New York. The donor of the Charles L Mayer Awards had in mind 'the vast possibilities offered for research on the action of chemical agents and physical factors in stimulating or retarding cell growth'. The National Science Fund will consider studies of factors controlling the growth of protozoa or animal tissue cultures or of entire organisms as eligible for awards. William J Robbins DSc, chairman of the National Science Fund of the National Academy of Sciences, stated that the committee is interested primarily in fundamental studies on the factors influencing growth of animal cells rather than applications to any particular aspect of normal or abnormal growth. According to Dr Robbins applications based on such studies may develop in the future, but at present we need more knowledge of the essentials concerned. Dr Robbins stated that the Mayer awards apply to the field of animal cell growth and that the advisory committee will welcome suggestions at once as to outstanding published contributions and manuscripts of 1942 on any phase of this subject. Communications should be sent to the National Science Fund offices 515 Madison Avenue, New York.

Regional Meeting of College of Physicians—The regional meeting of the American College of Physicians was held at the Drake Hotel in Chicago, November 21. Among the speakers were:

- Dr Nathan S Davis Chicago Treatment of Arterial Hypertension with Aortic Acid
- Dr Clifford J Barboraka Chicago Nutritional Problems in Wartime
- Dr Carl A John on Arthur Wil on Smith and Thomas J Coogan Chicago Effect of Altitude on Peripheral Circulation
- Drs Paul S Rhoads Evanston Ill and Melvin L Afremow Chicago Significance of Joint Pains Caused by Sterile Streptococcus Toxin
- Dr Roscoe J Sencenich South Bend Ind Maintaining High Standards of Medical Practice with Decreasing Personnel
- Dr Francis D Murphy Milwaukee Acute Nephritis and the Effect of Sulfonamides on the Kidney
- Dr Henry H Turner Oklahoma City Persistence of Estrogen Induced Sexual Development
- Major Thomas Donald McCarthy M C U S Army Camp Grant Ill Army Casualties Honolulu Dec 7 1941
- Dr Lloyd H Ziegler Wauwatosa Wis Psychoneuroses in Wartime
- Dr Paul H Holmberg Chicago Bronchoscopic Observations in Atypical Pneumonia
- Dr Archibald L Hoyne Advances in the Treatment of Contagious Diseases
- Dr John S Coulter Chicago Physical Therapy in Civilian Defense
- Dr Ralph C Brown Chicago Gastrointestinal Disorders in the Armed Forces
- Drs Carl W Apfelbach and Ernest E Irons Chicago Aspiration Pneumonia
- Brig Gen Charles C Hillman M C U S Army chief of the professional service division office of the Surgeon General Washington D C Risks on the Firing Line
- Dr James L Paulin Atlanta Ga President Elect of the American Medical Association Syphilis Heart Disease
- Dr Walter M Boothby Rochester Minn Wartime Medicine
- Capt Robert E Dunnein M C U S Navy Bethesda Md Problems of the Internist in the Navy
- Dr Paul D White Boston Cardiac Problems in Wartime
- Dr Warren H Cole Chicago Shock
- Dr Eric Oldberg Chicago Head Injuries
- Col Fred W Rankin M C A U S Lexington Ky President of the American Medical Association
- Dr Frank V Meriwether Chicago Functions of the Public Health Service in the Present Emergency

Special programs were held November 19 and 20 respectively at Camp Grant and the United States Naval Hospital, Great Lakes.

(From Our Regular Correspondent)

Oct 31, 1942

The Annual Report of the Minister of Health

The report of the minister of health for the year ended April 1 last has just been published. The health services and the public have had to manage with fewer doctors, dentists and pharmacists and with substitutes for some of the drugs and other supplies to which they are accustomed. But normal and emergency services have been maintained at an official standard and, most important of all, the nation's stubborn good health continues. There has been no major epidemic and no falling away from nutritional standards. Nevertheless the warning is given that the strains of war are necessarily progressive. The people's good health has contributed in no small degree to the war effort. The minister claims that this owes much to the improvements in housing, health and other social services made between 1919 and 1939 and also to all that has been done in those twenty years to educate the public in health matters. Rationing and the Ministry of Food advertisements have created a new interest in a balanced diet and in the methods of preparing and cooking food so that the maximum salts and vitamins will be retained.

After a drop to the record low figure of 2.60 in 1940, maternal mortality rose slightly in 1941 to 2.76, but the rate for infection during childbirth and the puerperium fell to 0.47 per thousand total births, the lowest on record. Infant mortality in its turn rose to 3.9 per thousand live births, an increase of 3 on the figure of 1940 and of 9 on the record low level of 1939. On the other hand, the stillbirth rate, which in 1938 was 3.8 declined to 3.5, again a low record. Further the infant mortality for the first quarter of 1942 was 61 per thousand live births, the lowest recorded for any first quarter.

Throughout the war years the essential maternity and child welfare services have been well maintained. In the emergency maternity homes, operated under the evacuation scheme (from dangerous areas), 29,520 babies were born. The continuous progress made during the year in arranging for the welfare of evacuees is stated to be due largely to the policy of appointing welfare officers and organizers as field workers.

A Wider Clinical Study of Disease

The quinquennial Dr Isaac Gilchrist lecture was delivered at the University of Aberdeen by Prof J A Ryle, whose subject was 'The Progress and Present Aspects of Medical Science.' He made a strong plea for a wider clinical study of disease. The great discoveries of specific microbic agents of disease and specific deficiencies has had, along with their immense benefits, a peculiarly limiting effect on the vision and practice of many physicians, not excepting teachers. These advances had compelled neglect of the associated causal factors without which no disease could exist. In the past quarter of a century the main endeavor of medicine had been to discover new diagnostic methods, and countless improvements and precisions had been due to radiology, chemistry, bacteriology and endoscopy. These prompted a desire for still greater accuracy, with the result that objectivity had often overreached itself, while symptomatology, which should have benefited, suffered neglect.

At the end of the last war we were dominated by the bacterial hypothesis and sought to attribute peptic ulceration and many other diseases to infection originating in some remote focus, such as a tooth socket. At the beginning of the present war a deepening interest in etiology led us on (or back, for the older

physicians were much alive to these causal complexities) to the "multiple factor" hypothesis, and the concept of focal sepsis as a main contributor was largely discarded. In the case of duodenal ulcer we are accumulating evidence of the part played by such factors as age, sex, hereditary predisposition, physical type and temperament on the one hand and emotional and occupational stress and tobacco on the other. Under the influence of one or more of the last three factors (which somewhat similarly affect the neuromuscular behavior of the stomach) it may be suggested that there are persons endowed by one or more of the preceding five factors with a heightened susceptibility to the development of the characteristic lesion.

By diagnosis we should imply something much more comprehensive than a descriptive label—a 'thorough knowledge of the case'—not merely its momentary morbid anatomy but its living and continuing morbid physiology. At one time, as still holds for skin diseases, nomenclature and classification were the main objective of diagnosis. The nature or physiology of symptoms calls for much closer study. Though rarely taught as such many represent only an exaggeration or depression of the familiar symptoms of health. All symptoms are specific phenomena not for a structural change but for a physiologic process or disturbance referable to a variety of changes or stresses. Hunger pain, a symptom of disease, is an exaggeration of normal hunger. Duodenal ulcer is by no means its sole cause. The overobjective physician, too cursory in his analysis of the patient's disease, tends to associate symptoms and syndromes with fixed patterns of morbid change. Becoming too selective he often looks for what is not there and is apt to form opinions based rather on the bias of his branch or practice or therapeutic preferences than on a strict analysis of symptoms and of their special significance in the individual. The old errors of our too simple division into "organic" and "functional" disease can be traced to neglect of the principle that the first aim of diagnosis should be to discover the physiology of a symptom or functional error and only then to determine whether it is due to emotion or fatigue, to anemia to a mechanical irritation, to an inflammation or to an obstructive lesion any of which alone or in combination may cause it. Immense though its value to medicine, morbid anatomy often tempts us with its standard pictures and more explicit signs to take the wrong path first. Physiologic diagnosis should precede anatomic, pathologic or psychologic diagnosis. The first question should be 'What does this symptom mean?' not 'What is it a symptom of?' This approach encourages greater accuracy of thought. Declining it we become liable to the two commonest errors in clinical work—over-reliance on some objective method such as radiography and inability to think in terms of function even when confronted with what we are pleased to call functional disease. Thinking in terms of mechanism, infection or chemistry, we are too apt to adopt mechanical or chemical methods—appendectomy for rightsided colon pain or sulfonamide compounds for a fever, when change of habits, reassurance and symptomatic measures would often be better. Overobjectivity in diagnosis leads to excessive "routine investigation" which can be as bad for the mind of the patient as it is for the mind of the physician. The modern "complete investigation" may sometimes be helpful for some obscure condition but should not be regarded as scientific and praiseworthy because it is new.

Increased Underground Shelters Against Air Raids

The London underground railways have been extensively used as shelters against air raids. It is now announced that eight new tunnel shelters of the most modern type in the world have been added. They are 75 to 110 feet below the ground level and will accommodate sixty-four thousand persons. They are provided with canteens, medical aid posts and an examination room. A physician and nurses will be in attendance.

Throat and Nose Manifestations of Blood Diseases

At the Section of Laryngology of the Royal Society of Medicine Mr W M Mollison opened a discussion on the nose and throat manifestations of blood diseases. He chose for consideration bleeding of the newborn, essential thrombocytopenia, or purpura hemorrhagica, polycythemia vera, hemophilia, hereditary telangiectasia, or Osler's disease, agranulocytosis, leukemia, achlorhydric anemia, avitaminosis and glandular fever. Though the first three exhibit bleeding from the nose and gums, in the absence of any local cause it is the pediatrician who takes over the case.

Hemophilia has generally declared itself in the boy before the laryngologist is consulted. All operations are to be avoided. In suspected cases full examination of the blood must be made before any operation. Even a normal clotting and bleeding time do not always save the surgeon from disaster.

Osler's disease is rare but embarrassing. Bleeding occurs simultaneously from skin and mucous membranes, and several members of the family are affected.

Agranulocytosis occurs after ingestion or injection of certain drugs—aminopyrine, sulfonamides, sanocrysin, arsenical compounds and benzene. It is also seen after exposure to high voltage roentgen radiation. Because of inflammation and ulceration of the tonsils, palate and gums the disease has been called agranulocytic angina. It has a very high mortality. The patient is very ill with a high temperature, often out of proportion to the pharyngeal lesions. Death may occur in a few days. There is a chronic form in which treatment leads to temporary improvement in the blood picture. Patients have lived for two years or more. Even slight operations are apt to produce serious relapses with extensive ulceration in the mouth. Rigors produced in the course of the disease lead to enormous leukocytosis with cure. In a recent case a leukocytosis of 40,000 followed a third transfusion, and cure was immediate and permanent.

Leukemia produces severe ulceration of the tonsil and is distinguished from agranulocytosis and other tonsil ulcerations only by blood examination. The prognosis is fatal.

Dysphagia is one of the least frequent symptoms of achlorhydric anemia. Most of the cases occur in the asthenic type of woman, with hair prematurely gray in contrast to the dark eyebrows. The skin is pigmented but not icteric. Anemia is not obvious till a blood count is done. Treatment consists in large doses of iron and ammonium citrate, up to 240 grams (15.5 Gm.) daily. It is successful, but hydrochloric acid never returns to the gastric juice.

In 1919 Brown-Kelly described a symptom complex in women complaining of dysphagia, spasm at the entrance of the esophagus, smooth tongue, fissures at the corners of the mouth and a pale pharyngeal mucous membrane. Esophagoscopy showed a small circular lumen which could be opened easily with much relief. Similarly Paterson described a clinical type of spasmodic dysphagia and/or superficial glossitis. He also noted changes in the mucous membrane which tended to make it crack on passing a tube. The narrow lumen just below the cricoid appeared to be due to spasm of the cricopharyngeus muscles, which led to the suggestion that it could not relax.

Avitaminosis supplies two diseases with nose and throat manifestations: scurvy and rickets. Scurvy usually occurs between the ages of 6 months and 3 years. A hemorrhage over the frontal bone has been misdiagnosed as osteomyelitis. The laryngismus stridulus of rickets may be confused with other causes of stridor.

Glandular fever is characterized by sore throat and enlarged glands, at first cervical, later epitrochlear, axillary, inguinal and mediastinal. The last group produce cough and perhaps stridor. The blood shows a leukocytosis up to 60,000, of which 80 per cent are lymphocytes.

Animal Health and the Food Supply

At the annual conference of the National Veterinary Medical Association Dr W R Woolridge advocated in his presidential address a national animal health service. He said that probably over 60 per cent of dairy cattle were infected with one disease or another and that the figure could not be far in excess for sheep, pigs and poultry. Of all domesticated animals horses were probably the healthiest. A bold and coordinated animal health service would produce a considerable reduction of disease and material lessening of the monetary loss due to disease, which could not be assessed at less than \$250,000,000 annually. The task of the veterinary profession could be nothing less than the organization of an efficient service to minister to the welfare of all animals and to improve the quantity, quality and safety of foodstuff of animal origin.

Official committees and other bodies, however, continued to be set up to consider problems without the assistance of proper veterinary representation. The veterinary practitioners should be remunerated by the state. There were about two thousand active veterinary surgeons in Great Britain, but the work awaiting a national animal health service required double that number. He favored the establishment of an animal health corporation with governors appointed by the state.

SWITZERLAND

Oct 15, 1942

Measures Taken Against Typhus

The Swiss Health Office recently called attention to the necessity of taking measures against typhus. Although the threat is not direct, the possibility exists that the disease is carried into Switzerland by refugees, escaped war prisoners or deserters. The border health service of Switzerland has taken measures with regard to travelers coming from regions in which typhus prevails. Furthermore a strict health control has been ordered for all destitute and homeless persons and for all vagrants. The school children are to be examined periodically for louse infestation. The hygiene institute of the University of Zurich has

Incidence of Typhus

Europe		
Spain from Jan 1 to Dec 13 1941	645 cases	993 deaths
Germany from Dec 29 1940 to Dec 13 1941	194 cases	221 deaths
Hungary from Jan 1 to Dec 27 1941	268 cases	26 deaths
Rumania from Jan 1 to Dec 31 1941	1,800 cases	
Bulgaria from Dec 29 1940 to Dec 15 1941	19 cases	0 deaths
North Africa		
Algeria from Jan 1 to Dec 20 1941	10,929 cases	
Tunisia from Dec 20 1940 to Dec 14 1941	5,411 cases	
French Morocco from Jan 1 to Dec 27 1941	1,500 cases	

produced a protective vaccine against typhus. Prophylactic vaccination has been officially recommended for all persons who might come in contact with typhus patients. Since the Russian campaign of 1941, typhus has penetrated from eastern Europe and Poland to Germany and the incidence of the disease has increased in Bulgaria, Rumania and Hungary. Spain, where typhus appeared after the civil war, also had numerous cases of the disease during 1941. The official report of the Swiss Health Office gives the figures here tabulated on the incidence of typhus in different countries. The figures include as a rule only the cases among the civil population.

The Swiss Health Office reports also that the protective measures which were taken during the last war and after the cessa-

tion of hostilities protected Switzerland against typhus, although at that time this disease took a considerable number of victims among the armed forces and civil populations of the belligerent countries. In a few instances the disease nearly reached the Swiss border. The greatest danger of introducing the disease existed during the after war period at the collapse of the battle fronts. From 1914 to 1922 Switzerland had only 4 cases of typhus (1914 and 1920 1 case each, 1922 2 cases).

Foundation for Scholarships

A foundation for scholarships in biologic and medical studies has been set up in Bern. The foundation is under the supervision of the federal council. The stock capital amounts to 120,000 francs. In addition, seventeen scholarships of 5,000 francs each have been pledged annually. The scholarships are to last two or three years, thus the student will have time to show whether he is better suited for academic or economic work. The originators of this foundation are in addition to the Association of Swiss Physicians and the Swiss Society of Chemists, the great chemical and pharmaceutical firms of Switzerland. They hope with this foundation to serve their country and to promote the development of Swiss science. The suggestions for the foundation came from Professor Gigon of Basel and from Professor Murali of Bern, who is also the president of the new foundation. The foundation is located in Basel.

Professor Gigon has also made suggestions for the establishment of a Swiss academy of the medical and biologic sciences, which is to be supported particularly by the faculty of medicine of Basel. The firm of Sandoz in Basel, on the occasion of the twenty-fifth anniversary of its pharmaceutical department, donated 500,000 francs for the proposed academy.

Control of Medicines in Switzerland

An intercantonal office for the evaluation of medicines has existed in Switzerland for years. Recently the control of pharmaceutical specialties that contain hormones has been decided on in order to protect the public against misrepresentation. The physiologic institute at the University of Lausanne under Professor Fleisch, has been designated as the only governmental office for the assay of hormones. The intercantonal control office will permit the marketing of hormone preparations by the cantonal health departments only after the institute has issued a certificate. The only governmental assay office for vitamin preparations is the physiologic chemical institute of the University of Basel under Prof. F. Verzar.

Brief Items

The second medical mission of Switzerland to the eastern front departed some time ago from Bern. It consisted of sixty-nine persons, among whom were twenty-eight physicians and twenty-six nurses. The chief surgeon is Dr. Ruppanner, director of the hospital in Samaden.

The insulin supply of Switzerland made it necessary for the federal health office to place restrictions on its sale. A medical certificate with exact statements regarding the need of treatment is necessary in order to obtain insulin.

Personals

Prof. Emil Buergi, head of the department of pharmacology and toxicology and of medical chemistry at the University of Bern, celebrated his seventieth birthday.

Prof. Dr. K. Lenggenhager, director of the surgical clinic of the University of Bern, has been appointed a regular professor.

The head of the department of hygiene at the University of Zurich, Prof. Hermann Mooser, has been called to Barcelona to help combat typhus.

The following appointments were made at the faculty of medicine of the University of Geneva. Prof. Georges de Morsier

was made chief of the department of neurology, Prof. Oscar Wyss was appointed head of the department of physiology and Privatdocent Dr. Franz Leuthardt was appointed extraordinary professor of physiologic chemistry.

Prof. Dr. Alfred Labhardt, head of the department of obstetrics and gynecology in Basel and director of the women's hospital in Basel, has retired on account of age.

Prof. Dr. H. W. Maier, for many years head of the department of psychiatry at the University of Zurich, has resigned. Dr. Manfred Bleuler of the psychiatric clinic of Basel, son of the deceased psychiatrist Eugen Bleuler, was appointed as Maier's successor.

Deaths

Dr. Henri Carriere from 1916 to 1937 director of the federal health office of Switzerland, is dead. He became widely known by his activity in the international office of public health in Paris and as a member of the advisory committee on traffic in opium and other dangerous drugs of the League of Nations in Geneva. He repeatedly was the chairman of this committee.

Prof. Paul Clairmont, who from 1918 to 1941 had the chair of surgery in Zurich, died at the age of 66 of carcinoma of the prostate.

Prof. Carl Dorno died at the age of 77 in Davos. Dorno is regarded as the founder of bioclimatology. With his own means and from personal initiative he erected in Davos the physical-meteorologic observatory, and he was its director until 1926 when it was combined with the Swiss institute for alpine physiology and tuberculosis. Dorno has made valuable contributions to bioclimatology, particularly by his investigations on the significance of climate and meteorologic conditions.

Prof. Edwin Ramel, head of the department of dermatology in Lausanne, who became known by his investigations in the sphere of cutaneous tuberculosis and cancer, died at the age of 46.

Prof. Dr. Gustav Wolff died in Basel at the age of 76. He had been professor of psychiatry and director of the psychiatric clinic of Basel from 1904 to 1925.

Marriages

EDWIN W. SHEARBURN JR., Charlottesville, Va., to Miss Charlotte Ann Brubaker of Parkersburg, W. Va., in August.

FREDERICK WARREN GOODRICH JR., Catskill, N. Y., to DR. VIRGINIA C. HALL of Marietta, Ohio, in New York, July 9.

OLIVER KENNARD SCOTT, Framingham, Mass., to Miss Deborah Ann Hubbard of Elizabethtown, N. Y., July 4.

ROBERT H. COV, Mount Vernon, Ky., to Miss Bille Henderson Crawford of Knoxville, Tenn., in September.

DWIGHT PARKINSON, Washington, D. C., to Miss Elizabeth Haselden of Montreal, Que., Canada, July 15.

JAMES GIBSON LOGUE JR., Williamsport, Pa., to Miss Camille Jennings Woods of Charlotte, N. C., July 11.

JAMES SLADE RHODES JR., Williamston, N. C., to Miss Jean Cooke Jackson of Charleston, S. C., in July.

HORACE MARTIN GEZON, Grand Rapids, Mich., to Miss Elizabeth Brownlee of Pittsburgh, September 19.

JOHN ROGERS MAPP, Machipongo, Va., to Miss Sara Rebecca Moore of Pageland, S. C., August 21.

CLEMENT STORY DWYER, Boston, to DR. MARGUERITE LOUISE MCKAY, Bar Harbor, Maine, July 2.

WILLIAM WARREN DANIEL, New York, to Miss Susan Jane Petry of Syracuse, N. Y., August 8.

CHARLES BRADLEY NORRIS to Miss William Ernestine Stout, both of Charlotte, N. C., July 11.

JOSEPH EDGAR CROSLAND to Miss Mary Elizabeth Howard, both of Greenville, S. C., in July.

EUGENE B. CANNON, Roanoke Rapids, N. C., to Miss Dee Armfield in Asheboro, August 7.

EUGENE L. LOZNER, New York, to Miss Jean M. Cuhler in Boston, July 3.

Deaths

Barclay Wellington Moffat * Red Bank, N J, Harvard Medical School, Boston, 1916, formerly assistant professor of clinical orthopedic surgery at the New York Post-Graduate Medical School, Columbia University, New York, specialist certified by the American Board of Orthopaedic Surgery, Inc, member of the American Orthopaedic Association and the American Academy of Orthopaedic Surgeons, president of the Monmouth County Medical Society, fellow of the American College of Surgeons, served as a captain in the medical corps of the U S Army during World War I, medical director of the New Jersey State Commission for Crippled Children, associate attending orthopedic surgeon, New York Post-Graduate Medical School and Hospital, New York, attending orthopedic surgeon, Fitkin Memorial Hospital, Neptune, consultant in orthopedic surgery, Allenwood Sanatorium and Monmouth County Hospital for Tuberculosis, Allenwood, Children's Country Home, Westfield, and the Betty Bacharach Home for Afflicted Children, Longport, aged 52, died, October 28

William James Swift, Chicago, Rush Medical College, Chicago, 1904, member of the Illinois State Medical Society and the Association of Military Surgeons of the United States formerly a fellow of the American College of Surgeons, associate in medicine and assistant to the deans at his alma mater from 1906 to 1909, registrar at De Paul University from 1908 to 1911 instructor in operative surgery at the Chicago Polyclinic from 1909 to 1915 assistant professor of surgery at the Illinois Post-Graduate Medical School 1916-1917, assistant professor of surgery from 1919 to 1924 and later associate clinical professor at the Loyola University School of Medicine, was in command of the first Illinois Field Base Hospital during World War I, served as a major in the medical corps of the Illinois National Guard and as commanding officer of the medical detachment of the 124th Field Artillery, 33d division, retired with rank of lieutenant colonel aged 64, attending surgeon at the Alexian Brothers' Hospital, where he died, November 10, of carcinoma of the esophagus

David King Smith, Toronto, Ont, Canada, University of Toronto Faculty of Medicine, 1896, specialist certified by the American Board of Dermatology and Syphilology, fellow of the Royal College of Physicians of Canada and of the Royal College of Physicians of London, past president of the Canadian Branch of the British Association of Dermatology and Syphilology, member of the American Dermatological Association, one of the founders of the American Academy of Dermatology, in 1930 was elected president of the Academy of Medicine of Toronto, during World War I served as a lieutenant colonel with the number 4 Canadian General Hospital and later as officer commanding the Davisville Military Hospital, formerly assistant professor of medicine at his alma mater in charge of the department of skin diseases in the Toronto General Hospital from 1912 to 1923, aged 69, died suddenly, November 3, as the result of a cerebral accident

Frederick F Gundrum * Sacramento, Calif Johns Hopkins University School of Medicine, Baltimore, 1908 demonstrator in anatomy at the University of Pittsburgh 1909-1910 specialist certified by the American Board of Internal Medicine, fellow of the American College of Physicians, president of the California Academy of Medicine in 1937, vice president of the Board of Medical Examiners from 1913 to 1915 and of the California State Board of Health from 1915 to 1932 member, past president and secretary of the Sacramento Society for Medical Improvement, chairman of the medical advisory board number 7 during World War I, director of the North California Branch of the State Laboratory from 1912 to 1915 chief visiting physician at the Sacramento County Hospital from 1910 to 1919, secretary and member of the board of trustees of the Sutter Hospital, aged 61, died, October 23, of a self-inflicted bullet wound

Joseph Edward Lombard * New York, University of Vermont College of Medicine, Burlington, 1889, past president of the Harlem Medical Society, the Valentine Mott Medical Society and the New York Society of Anesthetists, member of the American Society of Anesthetists, Inc, American Association of Anesthetists, the International Anesthesia Research Society, the Associated Anesthetists of the United States and Canada and the New York Academy of Medicine, formerly director of anesthesia at the Harlem Hospital, Memorial Hospital, Lyng-in Hospital and the Lutheran Hospital, for many years anesthetist at the Fordham Hospital, at one time taught anesthesia at the Fordham University School of Medicine and the New York University College of Medicine, devised the glass nasal tubes known by his name aged 77, died, October 27

J Brown Loring * Chicago, McGill University Faculty of Medicine, Montreal, Que, Canada, 1883, M R C S, England, and L R C P, London, 1884, adjunct professor of clinical ophthalmology from 1906 to 1908, professor of clinical ophthalmology from 1908 to 1913 and assistant professor of clinical ophthalmology from 1913 to 1917 at the University of Illinois College of Medicine, member of the American Academy of Ophthalmology and Otolaryngology, the Chicago Ophthalmological Society Institute of Medicine of Chicago and the Society of Medical History, fellow of the American College of Surgeons, at one time on the staff of the University Hospital, assistant surgeon in the eye department of the Illinois Charitable Eye and Ear Infirmary from 1894 to 1909, aged 81, died, November 6, of cerebral hemorrhage and arteriosclerosis

James Wiley Bodley * Memphis, Tenn, University of Pennsylvania School of Medicine, Philadelphia, 1915, associate professor of surgery at the University of Tennessee College of Medicine, certified by the American Board of Surgery and a member of the founders group of that board, member of the Southeastern Surgical Congress, fellow of the American College of Surgeons served as a major in the medical corps of the U S Army during World War I and as chief surgeon of Base Hospital number 55 overseas, state commander of the American Legion and a brigadier general of the Tennessee State Guard, chief of staff, Baptist Memorial Hospital, attending surgeon, John Gaston Hospital consultant surgeon, Crippled Children's Hospital School and Hospital for Crippled Adults, aged 53, died suddenly, October 27 of heart disease

Annie Roche Elliott * Norristown, Pa, Woman's Medical College of Pennsylvania, Philadelphia, 1912, associate clinical professor of psychiatry at her alma mater, member of the American Psychiatric Association, specialist certified by the American Board of Psychiatry and Neurology, Inc, assistant physician from 1913 to 1934, superintendent from 1934 to 1936 and since then assistant superintendent at the Norristown State Hospital, consulting psychiatrist to the Sacred Heart Hospital, aged 55, died October 30, in the Montgomery Hospital of carcinoma of the breast with metastasis

Murdock MacGregor * Dickinson, N D Trinity Medical College, Toronto, Ont, 1897, past president of the North Dakota State Medical Association, past president and secretary of the Cass County Medical Society and the Tri County Medical Society, fellow of the American College of Surgeons, at one time mayor of Fessenden, formerly attending surgeon, St John's Hospital Fargo, at one time associated with the MacGregor, Hanna and Clay Clinic and the Dakota Clinic in Fargo, aged 70 died September 20, in St Joseph's Hospital of chronic myocarditis and hypertension

Rufus B Stolp * Kenilworth, Ill, Chicago Homeopathic Medical College, 1897, specialist certified by the American Board of Internal Medicine, associate in medicine at the Northwestern University Medical School, Chicago, a member of the draft board of the North Shore area during World War I, chief of the emergency medical service or civilian defense of Wilmette, one of the founders and first president of the Kenilworth Historical Society, on the staff of the Evanston (Ill) Hospital, aged 67, died, November 3, of coronary thrombosis

Frank H Clarke, Lexington, Ky, Medical College of Evansville, Ind, 1875, University of Louisville Medical Department, 1889, member of the Kentucky State Medical Association, at one time superintendent of the Eastern State Hospital, served on the staffs of St Joseph and the Good Samaritan hospitals, for many years on the staff of the Lexington Clinic, member of the board of trustees of the Sayre School for Girls, aged 89, died, October 27, of arteriosclerotic heart disease

Frank Julius Herbig, Bay Pines, Fla, University and Bellevue Hospital Medical College, New York, 1911, for many years physician for the Veterans Administration, chief of the tuberculosis division of the Veterans Administration Facility, served as captain in the medical corps of the U S Army during World War I, formerly surgeon, U S Public Health Service Reserve, at one time assistant medical director of the Seaview Hospital, Staten Island, aged 65, died, October 26, in Alexandria Va

Maurice L Ripps * Elizabeth, N J, University of Michigan Medical School, Ann Arbor, 1923, specialist certified by the American Board of Pediatrics, Inc, member of the American Academy of Pediatrics, fellow of the American College of Physicians, assistant attending pediatrician, Elizabeth General Hospital and Dispensary and St Elizabeth Hospital, consulting pediatrician, Alexian Brothers Hospital on the staff of the Sea View Hospital, Staten Island, N Y, aged 43 died, October 28, in the Neurological Institute of New York, New York, of hematoma of the brain following an exploratory operation

Frank Henry Weiss * Denver, Columbia University College of Physicians and Surgeons, New York, 1901, formerly professor of physiology at the Medico-Chirurgical College of Kansas City, Mo., and professor of pediatrics at the University of Kansas School of Medicine, served on the staffs of the Presbyterian, St. Joseph and St. Anthony hospitals and the Porter Sanitarium and Hospital, aged 67, died in October.

Fred Robert Hanna, Lapeer, Mich., Detroit College of Medicine and Surgery, 1931, member of the Michigan State Medical Society and the American Psychiatric Association, served in the U. S. Coast Artillery during World War I, formerly physician of southern Oakland County, medical superintendent of the Lapeer State Home and Framing School, aged 42, died, October 27, of coronary occlusion.

William Givens Ramsay, McAlester, Okla., University Medical College of Kansas City, Mo., 1903, member of the Oklahoma State Medical Association, served during World War I, physician in charge of the Oklahoma State Prison Hospital, at one time member of the election board of Pittsburg County, formerly surgeon in chief of the All Saints' Hospital, aged 69, died recently.

Henry Raymond Ringness * Lieutenant M. C., U. S. Navy, Washington, D. C., George Washington University School of Medicine, Washington, 1939, was commissioned a lieutenant junior grade in the U. S. Navy, July 18, 1941 and began active duty Aug. 7, 1941, was promoted to the temporary rank of lieutenant June 15, 1942, aged 30, was killed on Guadalcanal Island in an airplane battle with the Japanese, October 17.

Charles A. Nevitt, Lexington, Ky., Louisville Medical College, 1904, member of the Kentucky State Medical Association, consultant in mental cases to the city police department, at one time physician in charge of the Elmwood Sanitarium, formerly on the staff of the Eastern State Hospital, aged 69, died October 27, in St. Joseph Hospital.

Silas Osborne Barkhurst, Steubenville, Ohio, Western Reserve University Medical Department, Cleveland, 1888, member of the Ohio State Medical Association, formerly member of the board of U. S. Pension Examiners, on the staffs of the Gill Memorial and the Ohio Valley hospitals, aged 79, died October 23, of cerebral arteriosclerosis.

Frank Reynolds, Syracuse, N. Y., University of the City of New York Medical Department, 1887, member of the Medical Society of the state of New York, for many years a member of the staff of the Crouse-Irving Hospital, formerly on the staff of St. Joseph Hospital, aged 89, died October 25, of chronic myocarditis and arteriosclerosis.

William Martin Sheridan * Spartanburg, S. C., Jefferson Medical College of Philadelphia, 1921, specialist certified by the American Board of Radiology Inc., member of the Radiological Society of North America Inc. and the American College of Radiology, on the staff of the Spartanburg General Hospital, aged 46, died, October 30.

James B. Lewis, Waynesboro, Ga., Medical College of the State of South Carolina, Charleston, 1911, member of the Medical Association of Georgia, examining physician for the draft board of Burke County, for many years county physician, aged 54, died, October 24, in the University Hospital, Augusta.

Edward Eli Worl, Newark, N. J., College of Physicians and Surgeons, New York, 1891, superintendent, contagious disease division of the city board of health, formerly superintendent of the Newark City Tuberculosis Sanatorium, Verona, aged 83, died, October 30, of myocardial degeneration.

Warren E. Pinner, Camden, N. J., Jefferson Medical College of Philadelphia, 1928, formerly captain in the medical detachment of the 114th Infantry of the New Jersey National Guard, at one time medical adviser for the schools of Runnemede, aged 41, was found dead, October 23.

Henry Stevenson Wailes, Salisbury Md., University College of Medicine, Richmond, Va., 1901, for many years surgeon for the Pennsylvania Railroad, formerly on the staff of the Peninsula General Hospital, aged 69, died, October 16, of hypertensive cardiovascular renal disease.

Ernest L. Mattox * Terre Haute, Ind., Rush Medical College, Chicago, 1905, fellow of the American College of Surgeons, aged 62, on the staff of the Union Hospital, where he died, November 1, of circulatory collapse following an operation for acute intestinal obstruction.

Frank Jackson Crosbie, New Lexington, Ohio, Starling Medical College, Columbus, 1902, member of the Ohio State Medical Association, secretary of the Perry County Medical Society, health officer of Perry County, aged 74, died, October 17, of coronary thrombosis.

Charles Louis William Rieger * Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1907, associate in roentgenology at his alma mater, aged 63, on the staff of the Hahnemann Hospital, where he died, October 29, of coronary heart disease.

Albert Andrew Kohler * Akron, Ohio, Western Reserve University Medical Department, Cleveland, 1890, health officer of Akron from 1891 to 1893 and from 1896 to 1916, on the staff of the City Hospital, aged 79, died, October 16, of cardiovascular renal disease.

Francis J. Peter * Turlock, Calif., University of Nebraska College of Medicine, Omaha, 1904, formerly clinical instructor in electrotherapeutics and assistant clinical instructor in surgery at his alma mater, on the staff of the Emanuel Hospital, health officer of Turlock, aged 64, died in October of heart disease.

Napoleon B. Mariner, Belhaven, N. C., University College of Medicine, Richmond, Va., 1903, member of the Medical Society of the State of North Carolina, formerly served as a member of the school board of Belhaven and as mayor, aged 65, died, October 16.

Aaron H. Detweiler, Schuylkill Haven, Pa., Medico-Chirurgical College of Philadelphia, 1902, member of the Medical Society of the State of Pennsylvania on the associate staff of the Pottsville (Pa.) Hospital, aged 63, died, October 22, of arteriosclerosis.

John Charlton Bigony * Hinton, W. Va., Ohio State University College of Medicine, Columbus, 1928, served in the U. S. Navy during World War I, Chesapeake and Ohio Railway surgeon, aged 46, died, October 31, of coronary thrombosis.

Edward Matthias Kennedy * New Hampton, Iowa, State University of Iowa College of Medicine, Iowa City, 1931, member of the staff of the New Hampton Clinic, aged 36, died, October 4, in St. Joseph's Hospital of carcinoma of the maxilla.

Zack H. McKinney, Haskell, Ark., University of Nashville (Tenn.) Medical Department, 1910, member of the Arkansas Medical Society, on the staff of the State Hospital, Benton Division, aged 61, died, October 16, of cerebral hemorrhage.

James Thomas Henley, Douglasville, Ga., Atlanta College of Physicians and Surgeons, 1900, commanding officer of Base Hospital number 11 in France during World War I, aged 73, died, October 27, of myocarditis and nephritis.

Charles B. Wycoff, Jetmore, Kan., Kansas Medical College, Medical Department of Washburn College, Topeka, 1911, served as mayor, aged 59, died, October 9, in St. Anthony's Hospital, Dodge City, of uremia.

Richard S. Smith, Chicago, Howard University College of Medicine, Washington, D. C., 1904, aged 69, died, November 5, in the Provident Hospital of hypertrophy of the prostate and myocarditis.

John L. Denson, Cameron, Texas, Memphis (Tenn.) Hospital Medical College, 1898, served during World War I, aged 71, died, October 18, of arteriosclerosis and hypertension.

Edwin Hamill, Chicago, Rush Medical College, Chicago, 1888, member of the Illinois State Medical Society, aged 79, died, November 14, of angina pectoris.

KILLED IN ACTION

LIEUTENANT HENRY R. RINGNESS,
M. C., U. S. NAVY 1912-1942

CORRECTION

Bryan Lee Mitchell—In the obituary of Dr. Bryan Lee Mitchell, THE JOURNAL, November 28, page 1055, erroneously reported that Dr. Mitchell was a member of the staff of St. Francis Hospital, Evanston.

Bureau of Investigation

CEASE AND DESIST ORDERS

Abstracts of Certain Federal Trade Commission Releases

The work of the Federal Trade Commission, in helping to protect the public against misrepresentation or fraud in the medical as well as other fields, has been greatly extended by the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act. The Food, Drug and Cosmetic Act of 1938 added to the Food and Drug Administration's control of the advertising claims and statements made on the label of a medicine or on the carton or in the accompanying leaflet, whereas what might be termed collateral advertising, that which appears in circulars, newspapers and magazines and over the air, comes more actively under the purview of the Federal Trade Commission by virtue of the Wheeler-Lea Amendment.

THE JOURNAL has at various times commented on the activities of the Federal Trade Commission in this connection even before the Wheeler-Lea Amendment gave it its added rights. In some cases the Commission may accept from the person or concern involved a stipulation that the objectionable practices or claims cited will be discontinued. In other cases the Commission issues what is known as a Cease and Desist Order, in which the individual, manufacturer or distributor cited is ordered to cease and desist from practices which have been declared objectionable. In some cases the claims cited have been discontinued by the firms several months (or even longer) before the issuance of the order. Abstracts of some of the orders issued in 1942 follow in this form: name of product name of distributor, date of issuance of complaint, date of issuance of Cease and Desist Order and terms of order.

Dr Chase's Cushion Comfort and Dr Chase's Health Shoes—J. Freil son Shoe Company Boston complaint issued Nov 17 1941 order issued Aug 23 1942. Order prohibited the concern from using the term "Doctor" or "Dr" or any simulation thereof to describe or refer to shoes not designed or approved by a doctor or otherwise representing in any way that their shoes offer special features which are the results of medical advice and from using the word health or any word of similar meaning to describe shoes which have no special scientific or orthopedic features or otherwise representing that shoes of customary or usual construction have special health or corrective features.

Marlt Short Wave Diathermy—George S. Mogilner and James Walker trading as Ment Health Appliance Company Los Angeles complaint issued July 26 1941 order issued Sept 9 1942. Order prohibited misrepresentations that unsupervised use of their short wave diathermy device by the lay public for self-diagnosed conditions through self application in the home constitutes a competent and effective means and method for the treatment of numerous ailments including rheumatism arthritis neuritis, and other ailments and for the alleviation of pain resulting from such conditions and that such use of the device is entirely safe. Order further prohibited any advertising which might fail to reveal clearly that the device is not safe to use unless a competent medical authority has determined by diagnosis that the use of diathermy is advisable in the case and has prescribed the frequency and rate of application of the treatments and the user has been adequately instructed in the use of the device by a trained technician.

N A (also known as N A No 7 Vaseline and Nature's Aid)—Pitt V. James trading as The N A Company Laurel Miss complaint issued Jan 6 1942 order issued Aug 22 1942. Order prohibited the promoter from representing that his product is a powerful antiseptic or germicide or is other than a mild astringent and antiseptic that it is unequalled in stopping bleeding or will arrest venous or arterial hemorrhages that it is a cure for athlete's foot or eczema or has any value in the treatment of such disorders beyond giving relief from itching and irritation that it is a splendid iron tonic or that its use will prevent lockjaw or blood poisoning that it is an effective treatment for indigestion sour stomach ptomaine poisoning rheumatism or kidney diseases or has any substantial value as an internal medicine for the treatment of any bodily disorder. The composition of N A No 7 was reported by government chemists in 1937 to be essentially a solution of iron and magnesium sulfates water and small amounts of calcium manganese aluminum and phosphate. In the same connection this product was declared in a district federal court to be misbranded under the Pure Food and Drugs Act because of fraudulent claims on its label.

Peggie Moran Savon—Peggie Moran Company Inc. Hollywood selling principally to retail dealers and Irene Johnston Inc. beauty parlor operator Los Angeles complaint issued Dec 20 1940 order issued July 15 1942. Order prohibited misrepresentations that the soap possesses value in removing excess flesh from the body or from any particular part of it. The Federal Trade Commission found that the soap contained bentonite clay which conceivably might withdraw small amounts of water from the body through the skin but that they would be so small as to be negligible.

Renesol—The Renesol Corporation Maurice Goldberg and Charles Goldblatt, Managers New York complaint issued Jan 29 1939, order issued July 10, 1942. Following, the Commission's findings that each Renesol capsule contained some bicarbonate of soda and 1 grain of phenobarbital that the dosage recommended for the treatment was in excess of that advised by the medical profession that continued use of phenobarbital might develop a craving for the drug and that its employment in excessive amounts might produce toxic psychosis the order prohibited the Renesol concern from further disseminating any advertisements which failed to reveal that the use of this preparation in excessive doses might result in serious injury to the physical and mental health of the user. The Commission however stated that the advertisements need contain only the statement "Caution Use only as directed," provided that the directions for use wherever they appear in the labeling contain a warning to the same effect and provided further that such directions for use do not specify a dosage in excess of that recommended in the respondents' directions as revised during the trial of the case. It is worth noting also that earlier (September 1935) the Commission had ordered the Renesol Corporation to discontinue misrepresenting the therapeutic value of this treatment or of any product similarly compounded.

Roberta Blueberry Juice—Mar Gold Health Products Corporation Oak Park Ill complaint issued Oct 11 1941 order issued July 19, 1942. Order prohibited advertisements representing that this product has any therapeutic value in the treatment of diabetic stomach disorders ulcers, constipation impaired digestion acidosis anemia arthritis or liver trouble or has any property other than that of a beverage with a food value limited to that provided by blueberries. Order also prohibited representation that this juice contains organic mineral elements in quantities sufficient to supply any mineral deficiency that it is beneficial to the nerves particularly those of the heart that it has properties favorably affecting maintenance of mucus and other gland secretions or that it will increase energy or possess properties effective in beautifying the complexion building bone and teeth or repairing tissue.

Slendolds (or Slendolds Nu Form Capsules)—Gene Hughes Drug Stores and Eugene L. Hughes President both trading as Sacramento Pharmaceutical Company Sacramento Calif complaint issued Sept 22 1940 order issued July 13 1942. The Federal Trade Commission on finding, that this treatment will not remove excess fat without producing harmful effects ordered the Hughes interest to cease disseminating any advertisements which represented that their preparation is a cure or remedy for obesity or a safe competent or effective treatment for that condition or that its use will tone up the entire system turn fat into energy and reduce the body's excess fat without harmful results.

Sulfuraid 21—Barr Laboratories Inc. New York complaint issued Feb 13 1941 order issued Sept 22 1942. Order prohibited misrepresentation that Sulfur in solution which hitherto denied man's efforts to produce is now an accomplished fact that Sulfur water a source of all kinds of pain except headaches regardless of the cause or origin. They not only stop muscular articular and ligamentary pain but pain due to rupture of muscles contusions neuralgia tubes and tumors that Sulfuraid 21 is a cure for many forms of rheumatism and nervous exhaustion that through the use of Sulfuraid 21 in hot water baths sulfur is absorbed from the water through the skin and mucous membranes and has a general medicinal effect on the body that the addition of this product to hot water quickens perspiration and rapid elimination of bodily waste and helps to counteract acidity or that this product is the first successful effort to create sulfur in solution or when used in hot bath has any therapeutic effect on diseased conditions of the body.

United Short Wave Diathermy—United Diathermy Inc. New York complaint issued Feb 4 1941 order issued July 24 1942. Order prohibited the following misrepresentations that the device in question (essentially a portable cabinet containing means for generation of electrical short waves and their application to parts of the human body by means of insulated electrodes) is safe or harmless or has any value in treating arthritis characterized by an infection bursitis in acute stages sinus trouble in which there is a retention of pus or any disease or condition involving an acute inflammatory process that it is an effective treatment for rheumatism arthritis neuritis and similar ailments unless these are limited in the advertising to those disorders which do not involve acute inflammatory processes. The concern was further ordered to discontinue any advertising which failed to reveal clearly that its device is not safe to use unless a competent medical authority has determined by diagnosis that diathermy is advisable and has prescribed the frequency and rate of application of such treatments and a trained technician has adequately instructed the user how to employ the device. The Commission emphasized that the unskillful use of any such mechanism might burn or otherwise seriously injure the person to whom it is applied and in cases of advanced blood vessel changes of the legs might in excessive dosage not only cause serious burns but lead directly to gangrene and necessitate amputation of the leg.

Willat Melmed of Heatless Permanent Waving—Irvin A. Willat trading as Heatless Permanent Wave Company San Francisco complaint issued Jan 7 1942 order issued Sept 27 1942. Order prohibited misrepresentations that any method of heatless permanent waving which includes the use of a curling solution of ammonium hydrogen sulfide constitutes a competent or scientific means of producing permanent waves or that such use will have no ill effects on the body or any advertisement which fails to reveal that use of such type of curling solution may cause local skin irritation nausea or vomiting convulsion a phyvation or collapse in the absence of ventilation and which if introduced into the circulatory system in sufficient quantities and strength may result in systemic poisoning and death.

"THE ROLE OF PHYSICAL THERAPY IN THE EARLY TREATMENT OF POLIOMYELITIS"

To the Editor —In the article of Dr H R McCarroll entitled 'The Role of Physical Therapy in the Early Treatment of Poliomyelitis' (THE JOURNAL, October 17, p 517) statistics are cited purporting to show that no treatment is better than any treatment in the care of this disease. When he attempts to include the Kenny work in his generalizations Dr McCarroll is drawing conclusions which are not based on facts known to him. Dr McCarroll admits that in this study there have been no cases treated by the Sister Kenny method.

Dr McCarroll says 'It has been my privilege to visit briefly the various hospitals in Minneapolis and see some of the cases treated under Sister Kenny's supervision.' The actual personal acquaintance of Dr McCarroll with Sister Kenny extended over a period of approximately two hours. During this brief time it would obviously have been impossible even for Miss Kenny to demonstrate, much less prove, her contention that the true symptoms of the disease of poliomyelitis had not been recognized previous to her work. As a matter of fact, Dr McCarroll has completely missed this main point of his visit. Miss Kenny's discovery is definitely not that there is a cure or even a treatment for the paralysis of poliomyelitis but rather that there are muscle conditions which are far more damaging to the bodily mechanics if unrecognized and untreated than is paralysis. Dr McCarroll could not possibly have found a satisfactory treatment for the disease of poliomyelitis if he has neglected to acquaint himself with the true symptoms of the disease.

Miss Kenny has decisively proved her point to those who have taken the time during the past two and one-half years to observe her work. Miss Kenny has brought to us the only physical therapy which could have been effective in treating the disease of poliomyelitis, since it is based on the symptoms which she alone discovered. Miss Kenny would be the first to deny that she claims any cure for paralysis. The patients in her hands and those of her trained assistants do, however, have remarkably little disability following treatment in spite of paralysis.

JOHN F POHL, M.D., Minneapolis

SERUM SICKNESS AND ANAPHYLAXIS

To the Editor —The editorial "Serum Sickness and Anaphylaxis in Man" in the October 17 issue prompts the following comment.

You quote "Kojis believes in the prophylactic value of routine administration of 5 minims (0.3 cc) of a 1:1,000 solution of epinephrine to every patient before serum is given regardless of his state of sensitivity." This is insufficient because of the evanescent action of epinephrine, which wears off within a few hours. How will the patient be protected against the delayed reactions and dangers?

In Queries and Minor Notes in THE JOURNAL, Oct 31, 1936 you published a communication from me on the same subject. In my comment then, which holds good today, I wrote that epinephrine alone injected prior to a serum injection is insufficient as a complete preventive for serum sickness because of its short duration of action. In addition, my procedure has been to administer orally an ephedrine and phenobarbital combination two hours after the epinephrine injection repeating

this combination every three to four hours for three to five days, depending on the case. This routine then controls the later disturbances of the serum. Certainly inject epinephrine fifteen minutes before the serum for the immediate danger, but fortify your patient with the ephedrine combination for the later dangers.

DAVID LOUIS ENGELSHER, M.D., New York

EXPERIMENTAL CIRRHOSIS OF THE LIVER

To the Editor —We wish to express our appreciation for the recent editorial mention (THE JOURNAL, October 24 p 624) of our studies on experimental cirrhosis of the liver. From this editorial, however, those who are not familiar with the study might infer that the detailed analysis of the dietary factors involved in the pathogenesis of this disease should be credited exclusively to our work. In order to avoid any possible misrepresentation we would like to call attention to the fact that although chronologically later, but certainly in independent investigations, several other groups of authors reached conclusions similar to those discussed in the editorial.

The entire group of relevant papers is as follows:

- Georgy Paul and Goldblatt Harry *Proc Soc Exper Biol & Med* 46 492 (March) 1941
- Webster Graham *J Clin Investigation* 20 440 (May) 1941
- Blumberg Harold, and McCollum, E V *Science* 93 598 (June 20) 1941
- Lillie R D, Daft, F S, and Sebrell, W H *Pub Health Rep* 56 1255 (June) 1941
- Daft F S, Sebrell W H and Lillie R D *Proc Soc Exper Biol & Med* 48 228 (Oct) 1941

Cleveland

KERATOCONJUNCTIVITIS

To the Editor —With regard to the editorial comment in THE JOURNAL, October 17, on the epidemic of keratoconjunctivitis which has been particularly prevalent on the Pacific coast, I should like to add that in my hands a 4 or 5 per cent solution of sodium sulfathiazole sesquihydrate has been almost specific. In the County Hospital here in San Diego many cases have been treated with this drug most successfully. As it is spreading over the nation it occurs to me that many men will try the ordinary treatment of 'pink eye,' which I first tried with most unsatisfactory results. Of my office patients (and I have had many) few have had to return after the first prescription, but I do suggest that it be continued for at least five days after all symptoms have disappeared else there may be a return, though in a somewhat milder form.

F J WALTER M.D. San Diego, Calif

PULMONARY ATELECTASIS

To the Editor —Referring to Dr de Takats' article in THE JOURNAL, October 31, regarding pulmonary atelectasis it is noted that there is some difference of opinion as to the desirability of using atropine for fear of its influence in diminishing and thickening the bronchial secretion, though it is agreed that its antispasmodic effect is desirable. Older clinicians know of Delafield's 'emphysema mixture.' Dr Delafield knew how to overcome the undesirable atropine effect while making use of the desirable antispasmodic effect. He included in his mixture potassium iodide which has the effect of thinning the sticky mucus thus promoting excretion, combined with relaxation by atropine. Potassium iodide is promptly excreted through the bronchi, and, when necessary, may be given intravenously.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts Revocation of License for Gross Immorality and Malpractice—The defendant physician was born in Hungary and in 1926 was graduated from the University of Leipzig with a degree of Doctor of Medicine. He came to this country, received his "first papers" under the naturalization laws in 1931 and was licensed to practice medicine in West Virginia the following year. He was thereafter employed by the superintendent of the Huntington State Hospital and in 1935 went to Williamson, where he practiced his profession, associated with the Mercy Hospital. Subsequently the plaintiff, Mingo County Medical Society, Inc., instituted a statutory proceeding before the West Virginia Public Health Council to revoke the defendant's license. The council found the defendant guilty of gross immorality and malpractice and revoked his license. The circuit court affirmed the order and the defendant appealed to the Supreme Court of Appeals of West Virginia.

The charges on which the defendant was found guilty were, in substance, that in July 1936 he testified before the Public Health Council, in a hearing on charges against him for professional misconduct, that he was a naturalized citizen of the United States when in fact he was not, that after an action for malpractice brought against him in the circuit court of Mingo County the action was continued generally after the defendant presented to the court a purported affidavit of the patient stating that the action was without foundation and releasing the defendant from all liability in connection therewith in consideration of the payment of \$150, when in fact the patient neither executed the affidavit nor received the money, that in a proceeding to subject debts owing to the defendant to the lien of an execution on a judgment against him he approached one of his debtors and requested him to testify under oath that the debt had been fully paid, and that when the defendant operated the Mercy Hospital he proposed an agreement to another physician by which such other physician would receive a percentage of fees obtained from patients he referred to the hospital. In addition, the council also found the defendant guilty of malpractice in that he treated a patient for a fracture so negligently, ignorantly and improperly that the patient will not recover from the injury.

The court could find nothing in the record to warrant disturbing the council's findings on the factual question as to malpractice, though the showing might be insufficient in a civil action for malpractice by a patient against his physician. A finding of malpractice, on conflicting evidence, by a board composed of physicians should be entitled to peculiar weight, the court said. As to the matter of gross immorality, the court believed that the finding on that question was entitled to the same weight as that on the question of malpractice. "Gross immorality," the court pointed out, should be measured by the standards of each profession, and in the medical profession, where the standards should admittedly be of the highest, where the lives of persons may depend on the integrity and honesty of the physician, the council was especially well fitted to determine what facts establish gross immorality.

The defendant contended that the charges on which he was found guilty did not mention "gross immorality" or "malpractice" but merely set out isolated and unconnected incidents. But, said the court, the Public Health Council in its findings and the circuit court in its affirmation referred to gross immorality and malpractice "as charged in the complaint." The defendant claimed, however, that he should have been furnished with a statement specifically charging him with gross immorality and malpractice. While it would no doubt have been better pleading to have alleged by way of conclusion that the charges constituted gross immorality and malpractice, said the

court, that omission was not fatal. Charges before administrative boards need not be stated with the technical nicety or formal exactness required of pleadings in court. Each of the charges against the defendant contained a statement of the facts on which the plaintiff expected to rely. The defendant was thereby fully informed of the charges against him and was served with "a statement of the charges" as required by the medical practice act.

The law provides that one member of the council shall be a dentist and two members chiropractors. The defendant complained because these three members were excluded from the hearing. It is only necessary to read carefully the statute, the court said, to see that the duties of the dentist and chiropractors as members of the council do not relate to the regulation of the practice of medicine. The defendant also pointed out that the provisions of law authorizing the revocation of a license are penal in nature and should be strictly construed and that therefore, when the law provides that the license of a person who is "guilty of a felony or gross immorality" may be revoked a finding of such guilt by a court or tribunal is a prerequisite to a hearing before the Public Health Council. As far as the conviction of a felony was concerned, the court agreed with the defendant's contention but pointed out that in the absence of a statutory definition of gross immorality the council could determine for itself, under the standards of the medical profession, whether a person has been guilty of such an offense.

The court therefore affirmed the judgment of the circuit court upholding the revocation order—*Mingo County Medical Soc., Inc. v. Simon*, 20 S. E. (2d) 807 (W. Va. 1942).

Pharmacy Practice Acts Physician Who Compounds Drugs for Patients Does Not Operate a Pharmacy—In 1934 the plaintiff, Medico-Dental Building Company, leased the ground floor of its building to the defendant to conduct a drug store. The lease provided that the plaintiff would not, during the life of such agreement, lease any other portion of its building "for the purpose of maintaining a drug store or selling drugs or ampoules." In 1937 the plaintiff leased an entire floor of the building to a physician who headed a group consisting of six or eight doctors. This lease provided that the premises were to be used solely as offices for the practice of medicine and dentistry. The lessee agreed that he would not "maintain therein or thereon, nor permit to be maintained therein or thereon, a drug store or drug dispensary, nor will lessee compound or dispense or permit to be compounded or dispensed, drugs or ampoules except in connection with the regular course of treatment of lessee's own patients." Subsequently the physicians employed a pharmacist and began purchasing drugs which were dispensed to patients of the group. Contending that this action constituted a violation of the promise made by the plaintiff, the defendant drug company vacated the premises which it had leased and the plaintiff thereupon filed suit for rent due. The trial court entered judgment for the defendant, and the plaintiff appealed to the district court of appeal, second district, division 3, California.

The trial court found that the plaintiff leased space to the physician "for the purpose of maintaining a drug store and selling drugs." This finding said the appellate court, was not supported by the evidence. The space was not leased for the purpose of maintaining therein a drug store. Its use for that purpose was expressly prohibited in positive language. The physician was given implied permission to compound and dispense drugs and ampoules in connection with the regular course of treatment of his own patients. Throughout the trial it was assumed that a physician who furnishes medicines to his patients is thereby conducting a drug store. That this is not true, said the court, is of common knowledge. The trial court also found that in his lease the physician was given permission to compound and "sell" drugs. Assuming, said the appellate court, that in a purely technical sense "selling" means every disposition except giving away without charge, direct or indirect, the compounding and dispensing of medicines and ampoules by a physi-

cian to his own patients in the course of treatment did not constitute the sale of drugs which was prohibited by the defendant's lease. In that lease it must have been the intention, said the court, to prohibit the carrying on of the business of selling drugs but not to prohibit those practices which as a matter of law, under their professional licenses, could be followed by physicians as such. Furthermore, said the court, the defendant drug company was in no position to complain. It knew of the activities engaged in by the group of physicians for several months during which it sold to the physicians the drugs they were dispensing to patients. The defendant's executives, observed the court, were not so naive as to believe that the physicians during the several months in question were purchasing large quantities of medicines and giving them away to their patients, for such is not the common practice among physicians. Equally significant was defendant's silence with respect to registering a complaint with the plaintiff until there arose some controversy over the amount of rent. The plainest principles of equity, concluded the court, precluded defendant from taking advantage of a situation which by its silence and acquiescence it encouraged.

The judgment in favor of the defendant was therefore reversed.—*Medico Dental Bldg Co of Los Angeles v Horton & Converse*, 124 P (2d) 56 (Calif, 1942)

Paternity Admissibility of Results of Blood Grouping Tests—The parties to this proceeding separated in September 1940. Twelve months later the defendant wife gave birth to a son. The plaintiff husband then filed suit for divorce on the ground of adultery, alleging that he was not the father of the baby born in 1941. The case was heard in the supreme court, Monroe County, New York.

At the trial the plaintiff denied having had sexual intercourse with the defendant after the separation in 1940. The defendant, on the other hand, testified to the contrary. During the pendency of this action, the plaintiff was granted an order, under section 306 a of the Civil Practice Act, requiring the defendant to submit the child to a physician appointed by the court, who made a blood grouping test of the blood of the child and the plaintiff. The physician testified as to his qualifications and experience and as to the advance of medical science in this field and then stated that, from the examination of blood which he made, the plaintiff could not possibly have been the father of the child born to the defendant in 1941.

To deny to the plaintiff a decree in this action, the court said would be tantamount to a holding either that the testimony of the physician was not worthy of belief or that the procedure for a blood test authorized by the Civil Practice Act is futile so far as having any probative value is concerned. No testimony was offered to impeach the physician's credibility or his ability and standing as a physician. He was selected by the court as a physician of experience qualified to make the tests.

In view of the circumstances of the case, the court felt justified in giving the testimony of the physician full weight. Accordingly, the defendant's motion to strike out the testimony of the physician was denied and the plaintiff's prayer for absolute divorce was granted.—*Schulze v Schulze*, 35 N Y S (2d) 218 (N Y, 1942)

Workmen's Compensation Acts Right of Employer to Require Employee to Take Medication in Connection with Physical Examination—The claimant, while in the course of his employment, was cranking a gasoline engine when the crank slipped and struck him on the base of the nose, a fracture resulting. Following the injury he suffered sphenoidal sinusitis, continuous headaches and an elevated temperature. For these injuries he was awarded compensation under the workmen's compensation act of Louisiana and this award was affirmed by the court of appeal. In that affirming opinion the court found that the claimant was suffering from sinusitis which was progressive and had grown worse since the injury, that laboratory tests made by physicians attending the claimant indicated the presence of malaria, that following such findings he

was given 200 grains (13 Gm) of quinine and an antimalarial preparation known as atabrine, that, although this treatment usually eradicates malaria, the claimant's fever persisted, and that complete relief from the sinusitis could never be obtained without the claimant's undergoing a major operation. Subsequently the defendants, the employer and its insurance company, filed a petition stating that the claimant had refused to undergo a course of quinine medication to determine whether or not his fever was caused by malaria. They asked the issuance of a rule requiring the claimant to show cause why compensation payments should not be terminated until such time as he submitted to a thorough and general malaria examination. The rule issued, the claimant excepted thereto, the trial court sustained the exception and the defendants appealed to the court of appeal of Louisiana.

The workmen's compensation act of Louisiana provides that an injured employee must submit himself, as often as may be reasonably necessary during the pendency of his claim for compensation or during the time he is receiving payments of compensation to examination by a qualified medical practitioner furnished and paid for by the employer. This requirement, the court pointed out, relates only to an examination, it does not require that the claimant submit himself for treatment, the theory being that the claimant has a right to be treated by a physician of his own choosing and not by a physician of his employer's choice. The claimant had previously submitted himself to an examination at the defendants' request. At that time an eye, ear, nose and throat specialist carefully examined him for sinus trouble, the condition which the court found to exist and on which its award was made. The specialist's report negated any kind of sinus trouble. Less than a month later the claimant again, also at the request of the defendants, presented himself for an examination and was hospitalized for two days. After other examinations were made the examining physician decided to try a course of quinine for the purpose of finding out whether such course of treatment would not reduce the fever. The claimant was within his rights in refusing to take the quinine, said the court. If it were held otherwise, there would be no end to what could be done under the guise of an examination. There are, for instance, tests and examinations which disclose tuberculosis. Under the defendants' contention, however, if such tests had been made and showed negative results, they would still have the right to confine the claimant in a tuberculosis sanatorium and force him to take treatment for tuberculosis. Malaria is not the only cause of fever, and if the claimant were required to take treatment for every disease that causes fever his treatment would never end until his own end came. The judgment of the lower court for the claimant was affirmed.—*Delafield v Maples*, 6 So (2d) 41 (La, 1942)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1912 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Heart Size in Children with Rheumatic Fever—Keith and Brick determined the changes in the size of the heart of 100 rheumatic children by comparing successive roentgenograms of the heart of the patient taken at various stages of a single attack of the disease. From two to twelve roentgenograms of the heart were taken of each patient. Ninety-six of the patients had rheumatic myocarditis, endocarditis or pericarditis, and 4 had doubtful signs of heart involvement. The surface area of the heart on admission was compared with that when progressive changes had ceased: the hearts of 33 became larger, of 18 remained unchanged and of 49 became smaller. Cross hatching, which indicates pericarditis with effusion, produced the greatest change in the size of the heart shadow. Acute dilatation with a dramatic change in the size of the heart does not seem to occur (except under rare circumstances). A moderate initial increase in the size of the heart can take place within two or three weeks, but enlargement occurs slowly at any stage of the disease. A fair increase or decrease may occur in five or six months, but the average change in this time is not great. When the change in the cardiac surface area in one month is more than 20 sq cm, pericarditis is probably present. Prognosis is better if the heart is getting smaller rather than larger. The heart muscle shows greater recuperative and improving powers than the heart valves. Usually the progress of a patient can be estimated better by studying the size of his heart than by studying the murmur. Bradycardia is more likely to produce cardiac enlargement than tachycardia, except in certain cases of paroxysmal tachycardia. The size of the heart decreases with continued rest in bed when there is no disease.

Sudden Death After Test Game—In reporting the death of a captain of an international rugby team who collapsed and died suddenly after having played a strenuous game, Cluver and Jokl state that postmortem examination revealed that a congenital development abnormality caused the fatal circulatory

crisis (coronary insufficiency) in this first class athlete. At necropsy the heart was found to be generally hypertrophied, weighing 482 Gm (17 ounces). The left coronary artery showed numerous atheromatous areas which had caused pronounced narrowing of the lumen at three places: at the orifice of the left coronary artery, the right coronary artery and along the anterior descending branch. The descending aorta measured a little more than half an inch in diameter, that is, it was less than half the normal size. A physiologic fall of blood pressure after the exercise must have occurred. Larger amounts of blood were shifted in the skin as a result of taking a hot bath. The oxygen requirements of the heart muscle were greatly increased after the exercise. It is probable that reflex spasm of the coronary artery was caused by the frustrated efforts of the diseased right kidney to expel its inflammatory contents. Permeability of the myocardial cell membranes was adversely affected by a concurrent respiratory infection. The observation allows a detailed analysis of a case of status thymicolymphaticus. The history of the patient can be traced back to the persistence of the thymus gland after puberty. Thus the arresting effect of this primary developmental disturbance on the maturation of the descending aorta can be understood. The latter anatomic deficiency explains the secondary pathologic reactions which caused death. The case emphasizes that even an extraordinarily high standard of physical efficiency is not a reliable indicator of the state of health. The twin brother of the deceased athlete had died two years before, also during exertion (swimming); postmortem examination was not possible, otherwise an attempt could have been made to prevent the second catastrophe. In view of the circumstances under which these twins died so suddenly, Wolf's suggestion that swimming and bathing should not be indulged in by those suffering from status thymicolymphaticus appears well founded.

Vitamin C in Childhood Infections—Abt and his associates studied the relation of vitamin C to infection in 145 hospitalized children. For controls 110 similar normal unhospitalized children were used. Seventy-six of the patients had scarlet fever, 17 acute rheumatic fever not involving the heart, 26 acute rheumatic heart disease, 16 were convalescent from acute carditis, 2 had chorea and 8 acute pharyngeal diphtheria. The ascorbic acid content of the blood plasma was determined two or three times a week. Alternate patients of the six clinical groups received daily 300 to 600 mg of supplementary ascorbic acid orally in addition to that contained in the regular hospital diet. The initial values for ascorbic acid of the patients with scarlet fever were significantly lower than those of the normal control group. The clinical course was not influenced by the large doses of ascorbic acid. In the patients with rheumatic fever, chorea and diphtheria the initial levels were not significantly different from those of the normal group. Though the plasma levels in the patients given supplementary ascorbic acid became higher than the levels of those on the unsupplemented diets, the course of the diseases was not affected by the supple-

mentary ascorbic acid. It is concluded from the study that high temperature alone does not significantly lower plasma ascorbic acid or increase to any great extent its utilization in the body. Fever accompanied by active infection, as in the scarlet fever group, may increase vitamin C utilization, which is reflected by a decrease in the plasma level and urinary excretion.

Vitamin E in Progressive Muscular Dystrophy—Pohl and Baethke treated progressive muscular dystrophy in 13 boys and 2 girls with vitamin E in the form of cold-pressed wheat germ oil, giving 1 teaspoon daily (equivalent to 55 mg of alpha tocopherol). At the end of five and a half months no improvement was evident, when the administration of a preparation of concentrated vitamin E (mixed natural tocopherols) in oil was begun. Each child was given a quantity of the vitamin concentrate equivalent to about 156 mg of alpha tocopherol. At the end of two and a half months of this therapy there was still no objective improvement. Therefore at this time in addition to the vitamin E 3 mg of thiamine hydrochloride and 25 mg of pyridoxine hydrochloride were given. Seven months on this combined vitamin regimen also resulted in no improvement. The authors concluded that if there was to be any support for Bicknell's report there must be some substance in whole wheat germ not present in the wheat germ oil that is effective in curing progressive muscular dystrophy. They therefore administered daily for seven months 2 ounces (56 Gm.) of the dried fresh whole wheat germ originally used by Bicknell, but still no patient was objectively improved. In all instances the progress of the disease was unretarded, as determined by tests of muscular strength. Five patients ceased to walk during the twenty-two months of observation. Subjectively, 5 subjects claimed that they did not tire as easily and that they were more energetic. The mothers of 3 patients thought the disease was not as rapidly progressive. Progressive muscular dystrophy remains an incurable disease.

Percutaneous Administration of Vitamin K—Conventional methods of administering vitamin K to the newborn infant are not ideal, because of the possibility of lipid pneumonia from oily solutions administered orally and encapsulation of the oily depot when injected parenterally. Vollmer and his collaborators tried percutaneous administration of concentrations of 0.01 to 1 per cent of menadione in eighty parts of liquid petrolatum and twenty parts of odorless kerosene. An exactly determined amount of the vitamin-oil mixture, usually 0.1 cc., was applied to the chest of the infant and distributed over the skin. Doses of 1 or 0.1 mg of menadione administered percutaneously during the first day of life were effective in preventing physiologic prothrombinopenia. A dose of 0.01 mg, percutaneously was effective in some infants and ineffective in others, while the same amount in sesame oil orally proved fully effective. Therefore, quantitatively more vitamin K is absorbed through the intestinal wall than through the skin. The speed of percutaneous absorption does not seem to be inferior to that of intestinal absorption and is probably superior to intramuscular absorption. In 1 newborn infant with clinical hemorrhagic disease and a prothrombin time of more than four minutes the bleeding ceased after four hours and the prothrombin time became normal six hours after the percutaneous administration of 1 mg of menadione. Prothrombinopenia was prevented in infants whose mothers received 1 or 2 mg of menadione percutaneously two to fifteen hours before delivery. The administration of vitamin K to mothers, though justified, should not be relied on for complete protection of the infant, as the hour of delivery cannot be predicted and the interval between administration and delivery may be too long or too short. Every infant should receive vitamin K immediately after birth, whether the mother did or did not receive it. Since 1 mg of vitamin K is about one hundred times the minimal requirement, it will be effective even when carelessly applied to the infant's skin. As hemorrhagic disease of the newborn is relatively rare and an intramuscular injection to every infant seems to be a too drastic step in dealing with such a remote risk, the simplicity of percutaneous administration may well render this valuable preventive measure acceptable as a routine procedure. It could be carried out simultaneously with the prophylactic instillation of silver nitrate solution into the eyes soon after delivery.

Bacteriology of Common Bile Duct—Elckles and Mirizzi studied the bacteriology of the common bile duct, gallbladder and duodenum of 75 patients on whom choledochotomy was to be performed. The choledochal bile was sterile in 41 of the 75 patients with disease of the extrahepatic bile ducts. Sterility of the choledochal bile was especially frequent in uncomplicated chronic calculeous cholecystitis and atrophic sclerosing cholecystitis, in 25 or 34 such cases. The results were similar in cases of empyema, or hydrops of the gallbladder when the gallbladder was the only organ involved by the disease. However, the choledochal bile was frequently infected when there were organic or functional complications. Infection of the common duct was present in 4 of 7 cases with stagnation of the choledochal bile resulting from dyskinesia or inflammatory stenosis of Oddi's sphincter in the absence of stone. In the remaining 3, macroscopic alterations of the choledochal bile existed. Stones in the common duct were the most frequent cause of infection of the choledochal bile. Infection occurred in 16 of 18 such cases. It seemed probable that in the 2 cases the calculus found during operation in the common duct was migrating from the gallbladder to the duodenum. The predominant bacteria in the various parts of the biliary system were *Escherichia coli*, which occurred in 72, and the streptococcus in 49. Other bacteria recovered were *Eberthella typhosa* from 8, *Pseudomonas aeruginosa* from 4 and staphylococci, saprophytes and associated bacteria from 13. The common duct is always infected when bacteria are found in other parts of the biliary system. The choledochal bile appears to have strong bactericidal power.

Acute Pancreatitis—The data that Lampson presents on 29 cases of acute pancreatitis were taken from the private and ward services of the Hartford Hospital from September 1938 to December 1941. The diagnosis was made at operation, at necropsy or on clinical evidence associated with an elevated urinary diastase as described by Foged. The test proved to be accurate. Of the 9 patients on whom operation was performed within three days there has been no patient with a positive test in whom there has not been evidence of pancreatitis. In the 10 patients operated on three or more, but within sixteen, days after onset the process had regressed so that gross pathologic

evidence of pancreatitis was not present. Ten patients had no operation, and 1 of these died, as did 3 of the 9 operated on within three days. This gives a gross mortality of 14 per cent. It is becoming more and more evident that hasty operative intervention in the extremely acute phase of the disease is a hazardous procedure. The evidence at hand is a 33 per cent mortality in the immediate operative group, as compared to a 5 per cent mortality in the combined nonoperative and delayed operative groups. The surgeon should deliberate carefully before contemplating celiotomy in acute pancreatitis. If operation is necessary, it is best undertaken during the less severe phase of the disease.

Treatment of Massive Esophageal Hemorrhage—Several procedures have been followed at one time or another for the prevention and control of profuse esophageal hemorrhage. These include dietary restrictions, local diathermy, local compression, injection of solutions onto the general circulation to stimulate coagulation, ligation, splenectomy, ligation of the coronary vein and the injection of a nonirritating yet sclerosing solution (quinine hydrochloride and ethyl carbamate) into the periesophageal or pericardiac plexus. Grace reports a case of advanced hepatic damage with ascites and esophageal varices, the latter ruptured, producing severe massive hemorrhage. An apparent hepatic fatality was avoided and the patient restored to good health by ligation of the coronary vein with injection of sodium morrhuate. The patient is now in good health and has no complaints. His hemoglobin is 96 per cent, and no ascites is present. A splenectomy was not considered because of the higher operative mortality of the intervention.

Gummatous Aortitis—Gordon and his associates describe the clinical and morphologic features of syphilitic gummatous aortitis. They report 3 of the 11 cases encountered among 360 cases of syphilitic aortitis recorded in the departments of pathology at the Boston City Hospital and the Massachusetts General Hospital. Gummatous aortitis usually has gumma formation in the media. In the series the gummas were usually of miliary type and could be definitely recognized only microscopically. They occurred as areas of necrosis involving both muscle and elastic tissues. The necrosis either was of the infarct type or was composed of structureless material containing nuclear debris. The form of the medial gummas conformed to the structures of the media, being roughly quadrangular or oval. At the periphery of such gummas were broad sheets of vascular granulation tissue which were heavily infiltrated with lymphocytes, plasma cells and some large mononuclear cells. Giant cells were present. The adventitia showed thickening where occasionally gumma occurred. The clinical features of gummatous aortitis are not specific or characteristic. Clinical diagnosis is difficult or even not feasible. The coexistent rheumatic condition (in 3 of the 11) may raise suspicion. In 1 of the 3, diagnosed macroscopically, the gummatous process completely occluded the right coronary artery and partially occluded the left one. In another the gummatous lesions were present also at the base of the aortic valve. In the third case an extensive gummatous process affected not only the aorta but the pulmonary artery, the necrotic gummatous lesions resulted in perforation of the aorta into the trachea. In none was there gumma in the myocardium. Gummatous aortitis is responsible for symptoms only if it leads to narrowing or occlusion of the coronary arteries or perforation of the aorta. In the 360 cases of chronic syphilitic aortitis, atheromatous changes over the

area affected by the syphilitic lesions were prominent. The diagnosis of gummatous aortitis can be suspected only in rare instances in young persons without aortic insufficiency but with a history of syphilitic infection in whom thoracic pain and rapidly progressing heart failure are associated with attacks of cardiac asthma and pulmonary edema.

Congo Red Test—Harmon and Kernwein believe that many problems in diagnosis of amyloid deposits might be clarified by the use of the congo red test. They present results of one hundred and thirty-nine injections of congo red in 69 patients. They have preferred to make a clinical and laboratory diagnosis of amyloid disease only when the dye was completely, and not only more than 50 per cent, removed from the blood after an hour. If complete absorption is adopted as the standard of a "positive" test the congo red test will have great significance. In the 8 patients in whom complete clearance of the dye occurred in one hour and who subsequently came to necropsy large quantities of amyloid were encountered in the organs. The presence of amyloid in the liver, spleen and other organs was confirmed at necropsy in 10 patients. The test indicated large quantities of amyloid in 8 other patients. 2 had a palpably enlarged liver at the first examination and 2 appeared to be recovering from amyloid disease as judged from the results of the dye test, disappearance of albuminuria and anemia and improvement in general well being and 4 had appreciable amounts of amyloid deposits as judged by the dye test but their livers and spleens were not palpable. The test should be valuable in following the course of amyloid disease. In recovery from this disease the positive dye test is the last sign to disappear. This occurs some months after the organs are no longer palpable and anemia and albuminuria disappear.

Hodgkin's Disease—In the case of Hodgkin's disease that Reimann and his colleagues present, the disease was suspected early in its course. Because the earliest and most prominent lesions were in the skin and demonstrable enlarged lymph nodes were not present, and because later microscopic changes in biopsies from the skin, lung, spleen and bone marrow were not classic or pathognostic, the possibility of chronic, relapsing, febrile, nonsuppurative panniculitis was considered. The condition conformed to this diagnosis except for the visceral involvement, its occurrence in a man, the occasional ulceration of a cutaneous lesion and its fatal end. As far as the cutaneous lesions were concerned it was panniculitis but with grave systemic involvement as well, all a part of the chronic granulomatous condition of Hodgkin's disease. The diagnosis was made only at necropsy when typical lesions of Hodgkin's disease in the abdominal lymph nodes were found to be associated with the microscopic changes in the skin and in the lungs observed at biopsy.

Retinitis in Diabetic Patient—Anderson suggests that the patient likely to acquire diabetic retinitis or one who already has the condition be treated early with diets relatively high in carbohydrates, low in fat and low in calories, together with adequate insulin if needed, so that long before arteriosclerosis has developed excessive stores of fat will have been reduced to

a minimum. This will prevent the hyperlipemia which is so common in the untreated or poorly treated diabetic patient. It will not prevent the eventual development of the fatty liver of lipocae deficiency. Arteriosclerosis and its retinitis may possibly be delayed by such a diet. Also the administration of lipocae may possibly accomplish this. When arteriosclerosis and its sequela retinitis have developed, the treatment should aim to avoid those physical states which favor evolution of the process and needless vascular accidents in already damaged vessels. The process may be partially stayed by scrupulously preventing unnecessary fat mobilization and inefficient fat metabolism by an adequate diet in carbohydrate and calories to maintain body weight which withholds all but a minimal intake of fat (about 45 Gm). Loss of weight or ketonuria indicates that the body is not sparing fat but is being driven to a most undesirable metabolism of the endogenous fat. The avoidance of vascular accidents can in part be accomplished by guarding against heroic reductions in blood sugar and moderating it only when it is associated with a gain in weight and/or persistent glycosuria. Adequate experimental appraisal of lipocae as a means of preventing arteriosclerosis in diabetes is awaited.

Treatment of Rhus Poisoning by Alcoholic Extracts—Clarke and Hanna used an alcoholic extract of Rhus toxicodendron to protect 14 boys from rhus dermatitis who were to spend the greater part of the summer of 1941 in a mountain camp where rhus dermatitis had been a yearly scourge. After a preliminary patch test, using a 1:500 or 1:100 dilution of the extract, each boy was given 0.05 cc. of the extract (in the fol-

lowing dilutions) subcutaneously at weekly intervals a 1:100, 1:50 and a 1:10 dilution and then two injections of the concentrate. Not 1 of the group was confined to bed because of rhus dermatitis. Of 107 other boys in the camp who received patch tests complete data were obtained on 82, of whom 71, or 86 per cent, had a positive reaction to the test. All of them were given prophylactic injections, 7 had the rash as severely as in previous years or more severely. 19 had a less intense or trifling eruption and 56 escaped entirely. Therefore in 85 per cent the prophylaxis was an apparent failure. Of the 35 who had had poison ivy in former years 7 had as severe a rash as in former years, in 12 it was less severe and 16 escaped the rash entirely. Of the 47 who had never had poison ivy dermatitis only 7 had a mild eruption and 40 escaped entirely.

Oral Prophylaxis Against Poison Ivy—Gold and Masucci state that the results of oral prophylaxis against poison ivy in 33 cases were disappointing in that the incidence of toxic cutaneous reactions was high and the desensitization obtained appeared to be of rather short duration, lasting in some instances only a few months.

Puerperal Sterilization—Since July 1939, according to Hewitt and McCall 267 women have been sterilized in the obstetric service of the Baroness Erlanger Hospital during the puerperium because of social or economic conditions, toxemia, heart disease or some other chronic disease. The Madlener, the Pomeroy, the cornual resection and the triple ligation techniques were employed. Of the 267 patients 161 were sterilized within twenty-four hours post partum but there seemed to be no appreciable difference in morbidity or complications when the operation was done later. Twenty-nine patients were morbid, that is, they had a postpartum temperature on two successive days of 100.4 F or more. There were 6 instances of endometritis and 1 each of thrombophlebitis, puerperal pyelitis, bronchitis and wound infection. The authors believe that the selection of patients for sterilization plays a greater role in subsequent complications and morbidity than the time at which they are operated on. The management during labor of candidates for sterilization is ultraconservative. The anesthetic of choice is local. Triple ligation of the tubes with a nonabsorbable suture is comparable in simplicity to the Madlener technique but failure is much higher, 6.1 as compared to 2.1 per cent. This difference can probably be explained on the theory that the sutures have been tied too tight, cut through the tube and afford it a better chance of canalization. Cornual resection probably offers the lowest percentage of failure and also has the advantage of preventing subsequent cases of salpingitis. However, it is time consuming and can be a bloody procedure. The Madlener technique is advocated because it is easy to perform and its results are relatively good. A follow-up on 215 discloses that 8 had subsequent pregnancies, a total failure of 3.7 per cent of the 8 women, 2 had been sterilized by the Madlener technique and 6 by triple ligation.

Sulfathiazole Locally for Infected Wounds.—The different sulfonamides do not have a specific action against certain bacterial species; their bacteriostatic effect on any species is directly related to the capacity of the compound to block the enzyme whose substrate is *p*-aminobenzoic acid. Their therapeutic effect when given by mouth is modified by their rate of absorption, but in local use the modifying factor is the solubility of the drug in tissue fluid. A real advantage of local treatment is that the danger of toxic effects is slight and the hazards of systemic sulfonamide treatment particularly renal complications, are thus obviated. The objections to local application are that pus and tissue exudates have an antisulfonamide action; their rapid absorption from the local site; the theoretical danger of local damage to the tissues by a saturated sulfonamide solution; the development of resistant strains of bacteria; and the fact that a sulfonamide applied locally penetrates only a few millimeters into the infected tissue and therefore may not reach viable bacteria, which are accessible via the blood stream. Experimental evidence strongly favors local treatment in localized infections. Clinical trial by Green and Parkin in 14 severely infected wounds showed an early and progressive response to energetic and sustained local treatment. Many of the wounds had failed to respond to other treatments, including sulfonamides by mouth. But with the intensive local application of sulfathiazole the infection subsided rapidly though the causative organism usually was not eliminated. Preliminary trials with warm sulfathiazole drip for local sepsis gave excellent results. When sepsis is deep it is obviously of great value to clear up the surface infection, so that surgical access is made safer. Local antiseptic treatment with sulfathiazole should be given an adequate trial. Penicillin and other powerful biologic antiseptics like gramicidin may later displace the sulfonamides but at present their place in local treatment appears to be for sulfonamide resistant bacterial strains. The most potent sulfonamide available should be used in prophylaxis as in established infections. The treatment in no wise displaces accepted surgical measures and is of no value in sepsis below an unbroken surface.

Isomer of Ephedrine in Prevention of Operative Shock.—Landau, Logue and Kopelman used pholedrine on 10 old or anemic patients or in long extensive operations in which severe shock becomes probable. Pholedrine, which is β -(*p*-oxyphenyl)-isopropylmethylamine, an isomer of ephedrine, was introduced as veritol, and the authors used a preparation called Stimatone. They have used it prophylactically to prevent the onset of shock (its use has been disappointing in air raid casualties with fully developed shock) and in "bad risk" patients, in whom severe shock is likely to develop despite adequate treatment. The drug can be given subcutaneously, intramuscularly or—if rapid action is desired—intravenously. It may be repeated many times without any weakening or suppression of its biologic action. Pholedrine was used with both inhalation and spinal anesthetics. With spinal anesthesia, 0.5 cc of pholedrine is given ten minutes before the spinal injection if a significant

drop in blood pressure occurs; a further 0.5 cc is given subcutaneously and the blood pressure is brought back to within normal limits. If the fall has been profound the blood pressure can be readily restored by 0.25 cc of pholedrine intravenously followed by 0.5 to 0.75 cc subcutaneously. Pholedrine does not replace adequate preoperative preparation by blood transfusion, saline infusion and other measures. Similarly, if it is to have its full effect during operation the blood volume must be maintained. Under these conditions other cardiac or respiratory stimulants were not necessary.

War Neurosis in Australian Forces in Tobruk.—From May 1941, when a war neurosis clinic was established in an underground concrete shelter in Tobruk, to August 207 men from the Tobruk fortress area were examined by Cooper and Sinclair, who followed the records of these men through British and Australian hospitals and convalescent depots. Of the 207 patients, 79 were returned to and are still with their units from two to four months since their return, 48, after treatment at the base, have returned to duty with a classification of fit for front line service and 48 are classified as fit for base duties. It appears that 4 out of every 5 men who break down under the stress of modern warfare are capable of returning for further useful service. The psychobiologic makeup of each of the 207 men had for the time being one dominating emotional reaction—fear, which was frankly appreciated and expressed by most of them. Thus fear reaction faded as soon as the massive stimulus producing it was removed. In some a morbid anticipation of bombing or shelling remained. In others fear laid the basis for the development of an anxiety neurosis. Before treating these men their full medical records should be obtained from the forward area, the regimental medical officer and from the platoon or company commander, information as to the patient's previous record in the unit, behavior under fire and the degree of psychic and physical trauma to which he was subjected. In all, 132 suffered from anxiety states, 34 from simple conversion hysteria, 5 from hypochondriasis, 9 from psychoneurosis, 10 from congenital mental defects, 4 from schizophrenia, 1 from psychotic depression, 2 from true exhaustion states and 4 from physical exhaustion, 6 were malingerers. The regimental medical officer can deal with most men in the early stages of anxiety neurosis or fear states by suggesting that certain men be given duties away from extreme stress, by talking to potential patients and in many instances preventing the anxiety state. Results depend on the cooperation of the soldier's unit and the army organization.

Percutaneous Treatment of Fractures—According to Hoffmann, the percutaneous treatment of fractures has advantages which have not all been utilized. The percutaneous device which he developed employs a ball and socket screw. It is based on the following principles: 1 Previous to the reposition a handy grip is attached to both fracture ends as far away from the fracture hematoma as possible. 2 These grips make it possible to control the fracture from outside and even under the fluoroscopic screen. 3 At the moment when the position of the fragments is satisfactory, the ball and socket screws attached to the grips and through which a steel rod is introduced, which bridges either the fracture or the joint, are tightened first with the fingers and then with a screw driver. Thus the fracture is reduced and fixed. 4 If it seems desirable to change the position somewhat, the screws of the ball and socket joints are merely loosened slightly. 5 The consolidation is controlled by loosening the ball and socket screws. The chief indication for this method is the open fracture of the diaphyses as well as of the metacarpophalanges inclusive of the elbow, knee and talocrural joints. The method fulfils the main requirement of absolute immobilization. It permits free access to the wound, avoids the offensive wetting of the plaster cast by exudates and does not bring a foreign body in contact with the wound, because the two grips are attached far from the fracture focus or from the injured joint. The use of the percutaneous ball and socket screw is advisable also in certain closed fractures, particularly if the dislocation is severe or if there is repeated slipping and the conservative method fails. It may be used as an aid in bone surgery and in orthopedics. The description of the structure and application of the apparatus are illustrated in diagrams. The chief modes of application of the apparatus are demonstrated. Several clinical cases are described and illustrated with photographs and roentgenograms. The author concludes that the method is easy to learn and is as harmless as wire extension

Heparin as a Therapeutic Against Thrombosis—Bauer employed heparin as a therapeutic rather than a prophylactic measure in thrombosis. He maintains that the drug should be withheld until thrombosis is definitely established. To insure early diagnosis he resorts to venography, which makes it possible to demonstrate the first manifestations of the condition in the lower leg. As soon as the diagnosis is established, heparin is given in large doses. The disease generally follows an abortive course. The author gives an account of all the cases of certain or of suspected thrombosis admitted to his hospital during the period from Oct 1, 1940 to Sept 30, 1941. Thirty-eight cases were diagnosed when the thrombotic process was still localized to the lower leg. They were treated with heparin, generally 100 mg three times daily for from three to five days, the total dosage averaging just over 1,100 mg. There were no deaths and no complications. The average length of time in bed after the beginning of the treatment was only 6.4 days. Thirteen cases were not seen until the thrombotic process had spread to the thigh. The doses here were somewhat larger than in the former group, the total averaging 1,540 mg. There was one death, due to pulmonary embolism. The average time

in bed was 7.3 days. In 6 out of 72 examinations venography did not decide with certainty whether thrombosis was present or not. These patients were treated with heparin, developed no complications, and were able to leave bed in a few days. In 15 cases clinical suspicion of thrombosis was ruled out by a definitely negative venogram. These patients received no heparin and were allowed to get up immediately. No signs of thrombosis manifested themselves later. By the use of heparin the treatment time for patients suffering from thrombosis was reduced to about one seventh that usually required. Mortality from thrombosis was greatly reduced and subsequent serious invalidism will probably be much decreased.

Size of Remaining Lung After Lobectomy and Pneumectomy—According to Husfeldt and Wandall the empty pleural space is often completely obliterated after lobectomy or pneumectomy. As contributing factors they list: (1) collapse of the thoracic wall by approximation of the ribs and decrease of the intercostal spaces, (2) elevation of the diaphragm, (3) displacement of the mediastinum toward the operated side and rotation of the heart backward into the lateral part of the costo-vertebral groove, (4) formation of an exudate which by coagulation and organization is transformed into a meshwork of fibrous tissue and (5) increase in the volume of the remaining lung tissue—the remaining part of the lung in the case of lobectomy and the remaining lung in the case of pneumectomy. It is this last phenomenon which the authors deal with in the following. The increase in volume which follows immediately after the operation may be due to emphysema or simple dilatation of the terminal respiratory units. Behrend and Mann have tried to explain the increase in volume as a mobilization of reserve material in the lung, presuming a constant play of open and closed lobuli in the lung in analogy with the open and closed glomeruli in the kidney. The present article is intended to demonstrate that Behrend and Mann's assumption cannot be correct and that their histologic pictures are misleading on account of inadequate technique. The authors made their studies on mice which have been killed by strangulation, whereupon the lungs have been removed with ligated trachea. Everywhere in the lungs the authors found open alveoli, bronchioles and ductuli alveolares, even if, before the strangulation, the mice stayed in an atmosphere with an oxygen content of 70 per cent, which should considerably increase the possible reserve material. This, however, only caused a decrease in the size of all the alveoli.

Acute Intussusception in Children—Edberg shows that roentgenologic examination has been of great importance in intussusception. The diagnosis has become more exact and the introduction of the contrast fluid by means of pressure enema is now a therapeutic method which largely has replaced laparotomy. The pressure enema was already recommended by Hirschsprung and is now enjoying a new vogue in a modernized form. The author reports his experiences with this treatment. His review includes 69 cases of acute intussusception. He regularly used contrast fluid pressure enemas. This method proved successful in 38 per cent of the cases. In 66 cases the intussusception was located in the ileocecal region. Three different types are distinguishable in this region: the cecoileocolic, the ileoileocolic and the type here called combined. The latter begins in the lowest part of the ileum and obstructs the passage into the cecum. The intussuscepted ileum together with the valvula Bauhini forms a combined caput. The first and the third type should preferably be treated by pressure enemas. The ileoileocolic type calls for prompt surgical treatment. Even this type can sometimes be completely desinvaginated by mechanical means. Although it is often possible to desinvaginate, at least partially, and fill the whole of the cecum with contrasting fluid, the physician may nevertheless remain uncertain whether the ileum has been effectively desinvaginated. In 11 cases relapses occurred. These 11 children were treated twenty-eight times for acute intussusception, fifteen times by means of pressure enemas only and thirteen times by subsequent laparotomies. It is obvious that the combined type has the majority of relapses. In this type certain anatomic variations in the lowest part of the ileum have been noted. The author considers them to be predisposing to the disease.

Book Notices

Standard Nomenclature of Disease and Standard Nomenclature of Operations Edited by Edwin P. Jordan, M.D. Third edition. Fabrikoid Press. \$1. 1 p 1022. Chicago: American Medical Association, 1912.

Uniform terminology is of the utmost importance in the advancement of medical science. The revised Standard Nomenclature of Disease and the new Standard Nomenclature of Operations are priceless contributions to the creation of uniformity in the designations by which diseases and operations are recorded in hospitals. Only by such uniformity can interchangeability of medical records among hospitals mean true insight into the history of the patient. Only by such uniformity can clinical research be conducted on a scale which correlates the experience of many institutions rather than being narrowed to the results obtained in a single hospital.

This edition embodies some 3,500 additions, deletions and corrections in individual diagnostic entries, and the entries in the section on Disorders of the Endocrine Glands and Hormones, which appeared in the classification of the "Body as a Whole" in previous editions have been reclassified under the appropriate organs. It is therefore a drastic revision which makes necessary its universal substitution for the earlier printings. Dr. Edwin P. Jordan, the editor, and the editorial advisory board are to be congratulated on the accomplishment of a most valuable work.

The Standard Nomenclature was conceived by the New York Academy of Medicine, which in 1928 appointed the National Conference on Nomenclature of Disease, with representatives from the leading medical and health organizations in the country. Financial support was secured mainly from the Common wealth Fund, and the work was directed by Dr. H. B. Logic, executive secretary of the National Conference. The first edition was completed in 1933 and the second in 1935. The work of periodic revision was taken over by the American Medical Association in 1937. On March 1, 1940 the National Conference on Medical Nomenclature was held under the auspices of the American Medical Association, with Dr. Haven Emerson of New York serving as chairman. Following this, with the assistance of carefully selected committees and an advisory board, the third edition was completed and published during the present year. Closely associated with the work from its inception, and at present a member of the editorial advisory board, has been Dr. George Baehr, formerly chairman of the National Conference on Nomenclature of Disease and now chief medical officer of the Office of Civilian Defense.

The revised Nomenclature is most complete and is comprehensively compiled so that it can be used in any size institution. Two classifications are used: (1) the topographic, or the portion of the body involved, and (2) the etiologic, or the cause of the disease. These two classifications are indicated by numbers separated from each other by a hyphen. The first three digits indicate the anatomic site, the last three, following the hyphen, describe the etiologic agent.

The new Standard Nomenclature of Operations fills a dire need. In this field there has been great confusion, although several good systems have been in use in different places. To decide on a uniform terminology that would be acceptable to all has been a prodigious task, and the committee under the chairmanship of Dr. H. Perry Jenkins modestly disclaims having done more than to provide a basis for a standard nomenclature, stating that "years of usage will be required to bring about any real standardization in designating operations by a uniform terminology." It is an excellent basis, however, and will certainly speed standardization.

The members of the Committee on Operative Nomenclature drew on their own wide experience in compilation of terminologies, Dr. Jenkins having compiled the Terminology of Operations of the University of Chicago Clinics, Dr. T. R. Ponton being the author of An Alphabetical Nomenclature of Diseases and Operations and Dr. Bronson S. Ray having compiled, with the assistance of Miss Helen B. Lincoln, the New York Hospital Classified Nomenclature of Operations. Due consideration was also given to terminologies developed by the Western Surgical Association, the University Hospitals of Cleveland, the University of California, the Mayo Clinic and

the Duke Foundation, and substantial assistance was given by many individuals. The division of fundamental surgical operations into eight main categories—incision, excision, amputation, introduction, endoscopy, repair, destruction, suture and manipulation—was carried over to a large extent from the New York Hospital nomenclature. The topographic numbers follow exactly those used in the Standard Nomenclature of Disease. The operative procedure is substituted for the etiologic classification, which in the other nomenclature appears after the hyphen.

The instructions to medical librarians in the use of the Standard Nomenclature of Disease and Standard Nomenclature of Operations are most valuable and will help in perfecting the system in any hospital.

It is most gratifying to feel that we now have a common basis for our medical language which will be of great advantage in compiling statistics, in clinical research, in writing scientific papers and in many other ways. Every physician and every hospital should become familiar with this system and use it to the fullest extent, for it represents the best possible work on the subject in the present period.

Tratado de patología quirúrgica general. Por el Dr. Manuel Bastos Ansari. Second edition. Cloth. Pp. 879 with 489 illustrations. Buenos Aires: Barcelona, Madrid & Rio de Janeiro: Editorial Labor S. A. 1941.

The second edition of this fine work bespeaks its popularity. It is timely, practical and well systematized. The bibliography is exhaustive. The first part deals with traumatism in general and is divided into twelve subheadings (such as contusions, wounds, mechanical injuries, vascular traumas, injuries to the nerves, bones, articulation, the effects of gases in warfare and frostbite). This section is especially thoroughly prepared and concludes with a consideration of the complications accompanying the various traumatisms. The second part consists in a discussion of infections, and here again one finds thirty-one subdivisions comprising many important and timely subjects besides the recognized entities granuloma inguinale and botryomycosis. In the third part surgical dystrophies are discussed; it also embraces a variety of considerations such as the hereditary constitution of the individual, congenital malformations and dystrophies of all systems. The fourth or last part deals with tumors and discusses the varieties of neoplasms. Each chapter is followed by an alphabetically arranged bibliography which is thorough and up to date. The illustrations are mainly well executed photographs and photomicrographs. All in all, this is a splendid work, and those who read Spanish will find in it a fount of information.

Young People in the Courts of New York State. Legislative Document (1942) No. 55. Paper. Pp. 309. Albany: Williams Press Inc. 1942.

This is a report made to the legislature of New York State by a committee appointed to investigate the facilities for the care and treatment of children coming under the jurisdiction of children's courts as well as those from 16 to 18 years of age coming under the jurisdiction of adult correction. The point of this report, of course, is to suggest making changes in the present handling of cases of minors. The report is well presented and covers a great deal of ground, including practically all the statutes which have to do with criminal jurisdiction over children and minors, as well as covering the penologic philosophy which has now grown up with minors and children. An extensive chapter covers the history of juvenile courts and the way they operate in New York State, and there are excellent chapters on adolescents and "less than adult" offenders in other states. The material on adolescents and on youths contains a good deal of medical material, discusses the factor of intelligence and gives statistics with regard to criminology. There is also some discussion of wayward minor laws in other jurisdictions. There is one part of the book devoted to legislations recommended but not acted on, both those which have been reintroduced and those that have not, and there is another part devoted to considering various proposals about minors' courts and discussing American Law Institute proposals, along the lines of youth correction authority acts. The committee concludes with some rather general recommendations which tend toward the continuation of work on treatment and correction of delinquency in children and youths. Those interested in child psychiatry, even those who do pediatrics and have occa-

sional problem children brought to them, should find this work stimulating. In a way it is technical, and there is more of the medicolegal picture presented than any picture of straight medical or even psychiatric treatment of the offender, but it all contributes to the background of those who have to deal with problem children.

A Handbook of Allergy for Students and Practitioners. By Wyndham B. Blanton, M.A., M.D., Litt.D., Professor of Clinical Medicine and Chief of the Immunology Clinic, O.P.D. Medical College of Virginia, Richmond. Cloth Price \$3. Pp. 190 with 21 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1942.

In the pages of this book our present knowledge of allergy is telescoped in a well organized manner. It could be an excellent guide for a teacher to be used as an outline for developing his lectures on the subject. For students as stated in the preface it answers 'the need for a brief but inclusive text to be supplemented by conference quiz and clinical demonstration.' With merely the bare outlines of allergy found in this book well organized as it is, without the supplementary lectures necessary to understand the subject, it can be of little value to practitioners who have not previously had an excellent course in allergy. The manner in which the subject of immunization against hay fever is treated illustrates the limitations of the volume. While the subject is well organized under the headings of preseasonal, coseasonal and perennial treatment, each heading is given one brief paragraph. The total space devoted to this matter of major importance to the general practitioner is one and a half pages, a subject that the teacher of allergy would find difficult to compress into a one hour lecture. The appendix covers twenty-seven pages and contains instructions for the preparation of a "dust free" room (courtesy of Allergen Proof Encasings Company) and recipes for special diets reproduced by courtesy of the Ralston Purina Company.

Professional Adjustments II. By Gene Harrison, A.B., R.N., Educational Director, Druid City Hospital School of Nursing, Tuscaloosa, Alabama. Cloth Price \$3.50. Pp. 124. St. Louis: C.V. Mosby Company, 1942.

This book is of special value to graduate nurses and to student nurses approaching graduation and beginning to think seriously of their choice of one of the special branches of nursing open to the graduate registered nurse. The book deals adequately and at some length with social and economic trends and their relation to the nursing situation plus a chapter on taking personal stock before graduation. This is followed by chapters dealing with the choice of a career, including descriptions of ten principal fields of special service, a number of miscellaneous opportunities, and general chapters indicating how to procure and hold a position and other useful general information. Additional chapters have to do with professional organizations and activities in the nursing field including public relations. A unit of four chapters is devoted to personal problems of economic and social security and personal integration. There is an appendix dealing with the legal status of the nurse. Extensive bibliographies are given, and there is a good index. This book should be in the library of every nursing school and would be a valuable reference book wherever vocational guidance and counseling is being done.

Problems of Aging. Biological and Medical Aspects. Edited by E.A. Cowdry, Washington University, St. Louis. A Publication of the Josiah Macy Jr. Foundation. Second edition. Cloth Price \$10. Pp. 936 with 129 illustrations. Baltimore: Williams & Wilkins Company, 1942.

The increasing interest in the problems of the care of the aged made necessary a new edition of this book. Since the publication of the first volume, a National Advisory Committee on Gerontology has been established, and the U.S. Public Health Service has undertaken a nationwide survey of investigations on aging. The National Research Council has set up a Committee on Aging, and an American Branch of an International Club for Research on Aging has been organized under Dr. William deB. MacNider of the University of North Carolina. The present volume includes nine new chapters. The older material has been revised and brought up to date. As a source book of information on the problems of aging, with good bibliographies and with articles by recognized authorities, this book may be unhesitatingly recommended as the most authentic compilation of material in the field.

Nutrition and Chemical Growth in Childhood. Volume I. Evaluation. By Iele G. Macy, Ph.D., Director, Research Laboratory, Children's Fund of Michigan, Detroit. With a foreword by Hugo A. Freund, M.D., President, Board of Trustees, Children's Fund of Michigan. Cloth Price \$5. Pp. 432 with 67 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1942.

It will not be possible to evaluate this book properly until the second volume is available. Volume I, as the subtitle indicates, is simply an evaluation and summary of methods employed in a twenty year study of children's problems under the Children's Fund of Michigan. There is a clear exposition of the objectives and of the approaches, with an extensive bibliography. Also there is a complete tabulation of all the individual publications that have been issued since the project was initiated. Some of the important aspects of the problem are indicated by the chapter headings covering physiologic and chemical aspects of digestion, energy metabolism in childhood, metabolic balances and hematocchemical studies. Nearly a third of the total page space is devoted to descriptions of methods. It is evident that the project is even more comprehensive than has been apparent from the separate papers that have been published. The participants are to be congratulated on the magnitude of the accomplishment.

The Medical Applications of the Short Wave Current. By William Bierman, M.D., Mending, Physical Therapist, Mount Sinai Hospital, New York. With a Chapter on Physical and Technical Aspects. By Myron M. Schwarzschild, M.A., Physicist, Beth Israel Hospital, New York. Second edition. Cloth Price \$5. Pp. 314 with 87 illustrations. Baltimore: William Wood & Company, 1942.

The revised edition of Bierman's work on short wave diathermy will be welcomed by all who seek a well written and scholarly monograph on the physics, physiologic effects and clinical uses of this new physical therapeutic agent which has found widespread employment in recent years. The chapter on physics and technical aspects has been condensed to about one third of its former size to the definite advantage of the average physician, who is not interested in mathematical formulas and potential curves and the clinical chapters have been correspondingly increased. An excellent chapter on fever therapy has been added, in the development of which method the author has carried on considerable clinical and laboratory research. Sixty new drawings serve to show all varieties of technical application. The author emphasizes his conviction that short wave diathermy exerts its clinical effects on the virtue of its thermogenic character, and there is no proof of any specific action.

A Textbook of Histology. By Alexander A. Maximow and William Bloom, Professor of Anatomy, University of Chicago, Chicago. Fourth edition. Cloth Price \$7. Pp. 695 with 362 illustrations. Philadelphia & London: W.B. Saunders Company, 1942.

In accordance with the policy which has been followed since the appearance of the first edition of this standard textbook in 1930, a new edition has appeared after a lapse of four years. According to the preface the greatest changes from the previous edition are in the introduction and the chapters dealing with bone, nerve, spleen, the female generative system and the eye. The text is liberally interspersed with excellent illustrations. The color plates in particular are noteworthy, and the publishers deserve great credit for the excellent reproduction of fine shades of color. Recent advance in the field of histology may be gauged in part by the fact that of the nine references given at the end of the second chapter, eight bear dates of 1925 or later. This book holds its place as one of the leading text and reference books in the field.

Healthful Living. By Harold S. Dicht, M.A., M.D., Sc.D., Professor of Preventive Medicine and Public Health and Dean of the Medical Sciences, University of Minnesota, Minneapolis. With a foreword by Morris Fishbein, M.D., Editor, Journal of the American Medical Association, Chicago. Whittlessey House Health Series. Morris Fishbein, M.D., Editor. New edition. Cloth Price \$2.75. Pp. 199 with illustrations. New York & London: Whittlessey House, McGraw-Hill Book Company, Inc., 1941.

This edition enhances the usefulness of this readable book for lay persons, which in its previous edition enjoyed a well deserved success. It is a comprehensive, clear and easily understood presentation of the facts relating to better living. It is intended for the use of intelligent lay persons interested in the prolongation of years of useful living. As such, it completely meets the needs for which it is designed.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

IRRITATION OF SKIN FROM SULFATHIAZOLE PREPARATIONS

To the Editor—Two patients were recently seen with the picture of contact dermatitis, to whom powdered sulfathiazole had been applied for rather long periods of time. One was a middle aged workman whose hand had been injured. The contaminated wound had been sutured and dry powdered sulfathiazole used as a dusting powder. The wound had long since healed but the skin of the hand was swollen and the surface dotted with vesicles. There was considerable pruritus. The dry adherent powder was finally washed off with soap and water and cod liver oil ointment applied. For a time slight improvement was noted but the vesicles soon spread, became purulent and appeared on other parts of the body. The other patient was an elderly woman on whose feet an operation had been performed. Sulfathiazole was used as a dry dressing. After a time the wound edges became inflamed and hot wet boric acid packs were used. Vesicles soon appeared in the affected areas which became pustular. Pruritus was intense. Other maculopapular lesions appeared in the bend of the elbow and other situations which rapidly went through the stage of vesiculation to that of pustules. The condition became aggravated and extended to other areas of the body. Various antipruritic measures failed to relieve the distress for more than a few minutes at a time. In view of the poor solubility of sulfathiazole in water, it is hard to understand how this drug could be the cause of this condition yet nothing else was used. There is no evidence of allergy in either patient and no history of any cutaneous lesions. Scratching might distribute the powder to other areas of the body but lesions could hardly arise unless the skin had become widely sensitized. This sensitization must have come about after prolonged absorption had taken place and yet aqueous solutions are not readily absorbed. Could boric acid in 1 case or mild soap and water in the other have modified the matter of solubility or decomposed the sulfathiazole? Or are these instances of acquired cutaneous sensitivity comparable with mercury formaldehyde and the like? Comments on these cases and pertinent references to the literature will be appreciated.

Ralph G. Mills, M.D., Decatur, Ill.

ANSWER—Instances of irritation of the skin both from sulfathiazole powder and from sulfathiazole ointment have been noted with some frequency.

It is believed that what happened in this case was that a localized dermatitis developed and then a generalization in the form of an infectious eczematoid dermatitis occurred as the result of the patient's scratching. In this manner it would be possible to transfer the dermatitis to other parts of the body.

It is not known whether this was a sensitization phenomenon which could be transferred to other persons. No doubt this would occur in a certain number. It is also not known whether boric acid or soap and water would modify the solubility of the sulfathiazole or decompose it.

In a situation of this sort, soothing measures would be in order, e.g. the use of compresses of 2 per cent aluminum acetate or of saturated boric acid solution, or perhaps even of potassium permanganate, later to be followed by soothing preparations like boric acid ointment or rose water ointment.

THYROID MEDICATION AND HYPERTENSION

To the Editor—Is thyroid medication contraindicated in a hypothyroid subject with essential hypertension? The basal metabolic rate runs constantly around minus 28 to 30 and the blood pressure is 150 systolic, 110 diastolic. Would thyroid medication have a tendency to elevate the blood pressure?

Earl H. Brown, M.D., Tucson, Ariz.

ANSWER—The treatment of hypothyroidism is the same whether it is complicated by essential hypertension or not. The basal metabolism should be raised to normal with slightly increasing doses of thyroid and a maintenance dose determined just as in any other patient with hypothyroidism. The only contraindications for giving an adequate maintenance dose would be development of angina pectoris or cardiac decompensation. Of course, in all patients over 40 years of age, particularly those with hypertension, the basal metabolism should be raised to normal slowly because of the possible presence of coronary disease, which may not be apparent when the basal metabolism is low. Specifically, the initial dose in such patients should not exceed one-half grain (0.032 Gm.) daily of U.S.P. thyroid. If the blood pressure is 150/110 when the basal metabolism is minus 28 to minus 30 per cent, it may rise slightly when the metabolism is raised to normal or it may show no change. However, a slight increase would not be a contraindication to the administration of thyroid.

SOLUTIONS FOR URIC ACID DETERMINATIONS OF BLOOD

To the Editor—What may be the cause of my difficulties with the determination of uric acid in the blood? I use the method of Herman Brown (*J. Biol. Chem.* 68:123 [April] 1926) with a glass standard from Hellige because I have not the facilities to prepare a reliable standard solution myself. When the reagents (Folin-Denis uric acid reagent, potassium cyanide Merck R. Gr.) were fresh the reaction worked reliably. But now about a year later it has been impossible to produce a color sufficiently deep blue to compare it with the standard. The potassium cyanide is kept in an ordinary bottle; the uric acid reagent apparently was not closed tightly enough because there were some crystal deposits on the outside around the stopper. Could that be the cause of the difficulties? How could I prevent the failure of the reaction otherwise? Should the solution be kept in special (alkali free) bottles? If the Folin-Denis reagent does not keep long could you suggest a method with a longer keeping standard (plus) reagent?

Felix Mottek, M.D., Cleveland Heights, Ohio.

ANSWER—It seems likely that the cause of difficulty has been the deterioration of the cyanide solution. Although potassium cyanide is mentioned, Brown in the paper to which reference is made, employed sodium cyanide (5 per cent solution of the J. T. Baker C. P. product). Sodium cyanide should be prepared fresh once in two months, and some workers think it desirable to make up fresh solutions every two weeks. The glass bottles were probably not the source of difficulty. The Folin-Denis uric acid reagent appears to keep indefinitely. The use of a glass color standard for uric acid is legitimate, provided the calibration is repeatedly checked against pure uric acid under the conditions used in the determination. Otherwise errors are certain to creep into the results. This is especially true here, where the intensity of color is dependent not only on the age of the cyanide solution but also on the particular preparation of cyanide used.

Since Benedict (*J. Biol. Chem.* 51:187 [March] 1922) observed that the color developed on uric acid with a uric acid color reagent (either that of Folin and Denis or of Benedict) was greatly intensified when cyanide was employed as the sole source of alkali, all the colorimetric uric acid methods have adopted the use of cyanide. On this account all the modifications of the Folin-Denis method (*J. Biol. Chem.* 14:95, 1913) require the use of a reasonably fresh cyanide solution, and this problem would not be altered by employing another modification of the Folin-Denis method.

ADRENAL CORTEX AND SPLENIC EXTRACT IN GLAUCOMA

To the Editor—I understand that in the past year or so certain cases of glaucoma have been successfully treated with standardized adrenal cortex and spleen extract. Will you please advise me of the present treatment of this condition and of any information you have on hormones and vitamins regarding it?

Douglas A. Jackson, M.D., Kansas City, Mo.

ANSWER—There have been several reports concerning the treatment of glaucoma with adrenal cortex and splenic extract. The following abstracts from the recent literature seem to give little support to those who claim remarkable results from the use of these preparations.

Woods (A. C. The Use of Extract of Adrenal Cortex in Glaucoma, *Arch. Ophthalmol.* 14:936 [Dec.] 1935) reported 12 cases in which adrenal cortex extract was given intramuscularly in 11 and intravenously in 1. The intraocular tension was taken immediately before the injection and at intervals of one-half hour up to four hours afterward. In 3 cases there was no change in tension, in 2, minor fluctuations, in 3, a rise which was apparently not related to the injection and in 3, minor falls in tension. In 5 cases concentration of chloride sodium and potassium in the blood plasma showed no alterations after administration of adrenal cortex extract. The author found no support for the theory of the pathogenesis of glaucoma advanced by Josephson or for therapeutic use of this extract.

Josephson (E. M. *Eye, Ear, Nose & Throat Monthly*, 13:453 [Jan.] 1935) advanced the theory that "adrenal cortex serves to render the capillaries less permeable to water of the plasma. In its absence there is an increased permeability of the capillaries to water of the plasma and the tissues become water soaked." Josephson reported 1 case of glaucoma simplex in which a tension of 42 mm. disappeared following an injection of adrenal cortex extract and an improvement in corrected vision from 20/30 to 20/15-2.

Adrenal cortex and splenic extract have been used by several ophthalmologists and a summary of their conclusions follows.

Lemone (A. N. Allergies in Ophthalmology, *Arch. Ophthalmol.* 28:79 [July] 1942) has stated that since in allergy there are loss of sodium and water and edema of the shock organ tissues, since the adrenal cortex regulates the sodium-potassium water balance and since the medulla reduces the edema of the

organ tissues, it stands to reason that a dysfunction of the adrenal gland must play a great part in the disturbed sodium-potassium-water balance and in the edema of the shock organ tissues in allergic manifestations

Adrenal cortex is a parasympathetic sedative, and it would seem that the hormones of these glands must be a factor in bringing about an imbalance of the vegetative nervous system

Goldenberg (Michael Splenic Extract in Glaucoma, *Illinois M J* 78 495 [Dec] 1940) stated that splenic extract is not a cure for glaucoma but that its greatest value is as a synergist to pilocarpine and physostigmine especially in the noncongestive type of glaucoma

Miller (E A The Treatment of Glaucoma with Splenic Extract, *Am J Ophth* 22 536 [May] 1939) believes that primary glaucoma is an angioneurotic edema within the eyeball, just as migraine is an angioneurotic edema of the brain He states that this is proved by the prompt relief of symptoms and reduction of intraocular pressure following the injection of a deproteinized extract of hog spleen He reports that therapeutic effects are not in proportion to the degree of the concentration of the splenic extract and favorable results can be obtained only if the extract happens to contain the curative element

Alvis (E B The Effect of Splenic Extract on Chronic Simple Glaucoma, *Am J Ophth* 23 529 [May] 1940) concludes that the administration of splenic extract in doses up to 20 cc daily is harmless but that the injection of such a large amount of fluid is rather uncomfortable to the patient In none of his cases in which splenic extract alone was tested did it hold the tension at a lower level than did the usual therapy of physostigmine and pilocarpine In 2 cases the tension rose as if no treatment at all were being given That it did not definitely go up without the usual miotics in all cases may have some significance Alvis states that, from the results obtained in his small series of 8 cases, it would seem that the value of splenic extract (40 per cent) in the treatment of chronic simple glaucoma is extremely doubtful

ANOREXIA IN YOUNG CHILD

To the Editor—A boy aged 2½ weighing 29 pounds (13 Kg) and 32 inches (81 cm) fall refuses to take any and all foods served It is necessary to feed him like an infant practically forcing him to take food into his mouth The food must be strained solid particles will cause him to gag and vomit The mother complains that the youngster is wilful and determined and will disregard any request if possible The past history reveals a normal delivery bottle fed baby with numerous formula changes in short intervals and bilateral otitis media The latter disorder confined the child to the hospital for two weeks during which time a transfusion of 300 cc of whole blood (father) was administered Recovery was uneventful X ray examination of the chest in the hospital revealed an enlarged thymus which disappeared three months after one x ray irradiation The physical findings are as follows (last examination made on Aug 4 1942) The general appearance is that of a pale youngster breathing through his mouth The skin is moderately dry His muscular control is not adequate for his age He walks or runs with considerable effort When running he throws his shoulders back and abdomen forward runs for a short distance and then asks to be picked up He walks for a short distance and then breaks into a run He falls readily The head examination reveals enlarged cryptic tonsils and a considerable amount of adenoid tissue A gland about the size of a small walnut can be seen and palpated on the inside of the sternocleidomastoid muscle on the left side The chest is normal both physically and roentgenologically The abdomen protrudes beyond the chest wall there is no evidence of distention however and it returns to normal when the child is lying down The lower extremities are normal throughout The feet are flat Spinal neurologic and orthopedic examinations are negative Laboratory examination reveals stool massive grayish white and containing no occult blood on several examinations The urine is normal The blood count reveals 4 million red blood cells and 75 per cent hemoglobin differential count is normal The parents are chiefly concerned with his anorexia and the necessity of feeding him strained foods Competent pediatricians accounted for this trouble on a neurotic basis and they considered the findings here enumerated as insignificant Your opinion and suggestions as to the management of this case will be appreciated

M J Antell Major M C, A U S

ANSWER—There are several possibilities in the approach to a case of this type A good deal of the child's difficulty may be due to enlarged tonsils and adenoids For this reason either roentgen treatments to the nose and throat or removal of the adenoids surgically may be done He would be considered too young for the removal of the tonsils without more specific reasons, e g repeated tonsillitis or obviously chronically diseased tonsils

Prior to this, however, the child should have a tuberculin test with an x-ray examination of the chest if possible It would also be well to place him on large doses of vitamins A, B, C and D, since he is probably suffering from a generalized

avitaminosis and seems to show some of the symptoms of rickets Finally the possibility of celiac disease or even some congenital anomaly of the gastrointestinal tract should be considered If the measures outlined fail to help, the celiac diet could be tried a diet high in proteins and low in fats and carbohydrates An anomaly of the gastrointestinal tract could be discerned only by a complete x-ray workup

In the absence of any pathologic reason for the continued anorexia, the best plan of treatment would be complete removal of the child from his present surroundings, especially the mother Such children often begin to eat heartily when temporarily placed in another home, preferably not with other relatives

The suggestions made are merely suggestions with a wish to be helpful, since the information sent is hardly sufficiently complete to warrant a diagnosis

DILATED RIGID PUPIL

To the Editor—What is the explanation significance, prognosis and treatment for paralysis of the pupillary constrictor muscle fibers of one iris? The other iris is perfectly normal The affected eye responds slightly if at all, to a bright light and there is no accommodation When light is flashed in the affected eye the pupil of the other eye contracts Eyegrounds, pressure visual fields muscle balance fusion and media are all normal Vision is 20/20 each eye with correction The patient is a young man, a college student who has been under terrific pressure of hard work for several months The Wassermann reaction, blood pressure, urine and general physical examination show nothing wrong No medications have been used in the eye at any time There is no paralysis of any other muscle The patient has no symptoms The enlarged pupil was discovered accidentally

Charles Taintor, M D, Port Jefferson L I, N Y

ANSWER—The presence of a dilated rigid pupil and loss of accommodation but presence of consensual reaction in the fellow eye can speak only for an internal ophthalmoplegia This is due to loss of function of branches of the third nerve and most frequently is of central (nuclear) origin If injury can be ruled out, some form of toxemia is the underlying cause Syphilis is a frequent factor, but almost any form of endogenous or exogenous toxin could thus affect the third nucleus

The dilated rigid pupil may cause an interference in accommodation that is not a real paralysis In such cases it is well to examine the pupillary margin for microscopic tears that extend through the sphincter pupillae and prevent the constricting reaction Such tears are usually the result of long forgotten blunt trauma They can be detected only biomicroscopically No treatment is of any value

If, however, the pupillary paralysis is of toxic origin careful search must be made for the source of the toxins, which must be eliminated Locally, some little benefit is obtained from the daily use of a weak pilocarpine solution

INGUINAL HERNIAS

To the Editor—There seems to be a difference of opinion among physicians as to the differentiation between complete and incomplete indirect inguinal hernias I would appreciate any information you can furnish on this

J L McClintock Major M C, A U S

ANSWER—Watson (I F Hernia ed 2, St Louis C V Mosby Company, p 145) defines an incomplete inguinal hernia as one in which the hernia or protrusion has passed through the internal abdominal ring into the inguinal canal, and a complete inguinal hernia as one which has descended through the inguinal canal past the external abdominal ring For practical purposes these are considered merely as degrees in the development of an indirect inguinal hernia A suitable description would be a small or a large hernia Both are hernias and both should be treated

UNILATERAL FACIAL PARALYSIS

To the Editor—A girl aged 18 had nasal diphreria when 2 years old resulting in unilateral facial paralysis which has shown little tendency to recover A neurologic surgeon proposed nerve grafting several years ago A surgeon in New York discredited the grafting and suggested the decompression operation but offered little encouragement regarding results, and for that reason no operation was performed Has any new operative procedure been developed which offers better cosmetic results than grafting or the decompression operation? M D Virginia

ANSWER—For years unilateral facial paralysis has been treated by fixing the inactive distorted muscles with strips of fascia lata which range from the temporal region down to the various points to be fixed This has been quite satisfactory, as the motion of the unparalyzed side of the face goes a long way to hide the fact that one side is paralyzed

THE "COMBINED OPERATION" IN LOW BACK AND SCIATIC PAIN

RALPH K GHORMLEY, MD

J GRAFTON LOVE, MD

AND

H HERMAN YOUNG, MD

ROCHESTER, MINN

We have reviewed records of a series of patients treated by what we at the Mayo Clinic call a "combined operation for low back and sciatic pain." This group of cases includes those in which one member of the neurosurgical staff has explored the spinal canal for evidence of an intraspinal lesion (and has removed it if it was found) and in which one member of the orthopedic surgical staff has carried out bone grafting to bridge the affected parts. The study includes the patients so treated in the years 1936 to 1940 inclusive. The procedure has gone through a period of evolutionary development from the time when operations for protruded intervertebral disk began to be performed in any number

NUMBER

The number of combined operations performed has increased somewhat during the years of this study. In the year 1936 no combined operations were performed in cases of suspected protrusion of an intervertebral disk. In 1937 1 per cent of the patients for whom laminectomy was performed also underwent a bone graft operation. In 1938 6.5 per cent, in 1939 14.8 per cent and in 1940 14 per cent of the cases in which laminectomy was performed for suspected protrusion of an intervertebral disk bone grafting was done. The increase in this percentage is due not only to the fact that both neurosurgeon and orthopedic surgeon felt that some patients with protruded disk should undergo bone grafting, but also to the fact that in many cases in which the orthopedic surgeon had planned a bone grafting operation he asked that the neurosurgeon perform laminectomy so that it could be determined whether or not a protruded disk might be present. In the latter group we particularly refer to cases of spondylolisthesis, spondylolysis and the like.

STATUS OF THE COMBINED OPERATION

It is safe to say that considerable difference of opinion may still exist as to the importance of a bone graft or fusion operation in connection with removal

of a protruded intervertebral disk. Many orthopedic surgeons, we are sure, believe that in most, if not all, cases such a combined procedure should be carried out. On the other hand it is probably true that many neurosurgeons feel that such combined procedures are not necessary.

It is our opinion that the surgeon can promise the majority of patients with protruded intervertebral disks relief by removal of the protrusion alone. However, it is also our opinion that there is a group of cases in which a bone graft or fusion operation should be done to relieve most of the symptoms and to give the best result.

REASONS FOR PERFORMANCE

Walsh and Love¹ in 1940 stated that "the patient who has a protruded disk and well developed spondylolisthesis should have fusion performed at the time of removal of the protruded disk. The patient who has associated spondylolysis probably should have fusion done at the time of surgical removal of the protruded disk. The patient who has extensive lumbosacral arthritis and a static type of backache in addition to a protruded disk and its resultant symptoms probably should have fusion done at the time when the protruded disk is removed."

It is the custom at the Mayo Clinic to have an orthopedic consultant see all patients suspected of having protrusion of an intervertebral disk before decision as to operation is made. In fact, in many cases two or more such consultations are held. The orthopedic surgeon, consulting the neurosurgeon, decides whether or not a fusion or bone grafting operation should be done. In general, the indications as outlined by Walsh and Love are followed. In many cases of congenital anomaly, such as sacralization, an anomalous neural arch or anomalous conformation of the body of the vertebra, in which there is an apparent instability of the vertebra in question, bone grafting will be done. In some cases judgment as to the instability and its importance is left until the time of the operation, at which, with the vertebral arches exposed, their stability is tested and the decision is made. If such instability is not found, the operation of bone grafting may be omitted.

It must be borne in mind that the roentgenographic appearance alone is not the determining factor in cases in which combined operations are chosen. A careful review of the patient's history must be carried out and the symptoms must be analyzed. It has seemed to us that in general only patients relieved by rest who have had recurrence of pain on resumption of activity will be suitable candidates for combined operation, provided, as noted previously, some evidence of instability

From the Section on Orthopedic Surgery (Dr. Ghormley), Section on Neurologic Surgery (Dr. Love) and Section on Orthopedic Surgery (Dr. Young), Mayo Clinic.

of the lumbosacral portion is found. This may be modified to such extent that patients who have a long-standing static type of backache and who have superimposed evidence of a protruded disk, the pain of which is not relieved by rest, may be advised to undergo the combined operation.

A review of the records in the series from this particular point of view reveals that approximately two thirds of the patients complained of backache of the static type. About a third of the patients had backache of a less well defined type. In 8 cases there was no definite history of backache.

From the neurologic point of view it might be noted that among the 77 patients who had a protruded intervertebral disk 33 had decreased achilles tendon reflexes, whereas 24 of the 62 patients who underwent exploration with negative results had a decreased achilles tendon reflex. In the group of 77 patients who had protruded intervertebral disks, results of spinograms were positive in 49 cases and results of examination

spinograms, may be unreliable because of previously performed operations, the decision to operate rests on the surgeons and their ability to distinguish a condition based on true organic lesions from a condition arising from a neurosis.

RESULTS

No attempt will be made herein to incorporate the many studies of end results which have been published in years past on the question of fusion operations alone. Ghormley and Wesson² in 1936 reviewed results of all fusion operations done at the Mayo Clinic up to that year for low back and sciatic pain, not including spondylolisthesis. In this review of the patients for whom lumbosacral grafting (from the iliac crest) was combined with sacroiliac fusion on the affected side, 72 per cent obtained good results. On the other hand, on those patients who underwent lumbosacral grafting alone only 56.5 per cent obtained good results when bone from the iliac crest was used, and only 66 per cent of those treated with bone from the tibia obtained good results.

Studies of the end results of operations of the combined type are few. Barr and Mixer³ reported that complete relief was secured for 77 per cent of all patients who underwent operation for protruded disk, with or without the fusion procedure. Ninety-one per cent of the patients on whom the fusion operation was performed in addition to removal of the protruded disk obtained complete relief, whereas in the group (from the same series) in which the protruded disk was removed without the fusion operations 69 per cent of the patients were completely relieved. The authors stated that "spine fusion at the time of laminectomy seems to give definitely better results than laminectomy alone." Bradford and Spurling⁴ said that "the use of spinal fusion in selected cases may well increase the number of satisfactory results" but gave no statistics with which to substantiate their statement.

Studies of the end results of removal of protruded disks alone are not very numerous. Love and Camp⁵ in 1937 reported the results obtained in 50 cases in which removal of protruded disks had been done. Thirty-three patients were completely relieved of the symptoms for which the operation had been performed. Fifteen were benefited by the operation but not completely relieved, and 2 patients secured no benefit from the operation. Craig and Walsh⁶ reported an additional group of 89 cases in which protruded intervertebral disks had been removed and wrote that good results had been obtained in 83.3 per cent of cases in which compensation was not involved and that unsatisfactory results had been achieved in 16.7 per cent of the same total group. In this group (in which compensation was involved) the percentage of good results was 59.1 and the percentage of unsatisfactory results was 40.9.

TABLE 1—End Results Combined Operation for 77 Patients Found at Exploratory Operation to Have Protruded Intervertebral Disks, 1936-1940 Inclusive

Diagnosis	Results Patients *			Not Traced	Total

with radiopaque oil were positive in 5 additional cases. Hence, for 54 of 77 patients with protruded disks results of myelographic examination were positive.

In the group of 62 patients for whom results of exploration were negative, results of spinograms were positive in 20 cases and in 1 case results of examination with radiopaque oil were positive. This apparent discrepancy between the results of the spinogram and results of surgical exploration is explained by the fact that, in this series, cases of thickened fibrotic ligamentum flavum in which results of spinograms may be positive have been grouped with cases in which results of exploration were negative.

There is also a group of patients who obviously have been seriously handicapped and have not responded to various types of conservative measures for whom exploration by the neurosurgeon has been carried out and for whom bone grafting has been performed. Another group of not too happy results is represented by those patients who have undergone previous operations of one type or another which have failed and for whom we have undertaken another operation. Decision to operate in these cases must be made only after the most careful analysis of all factors. Results of many of our examinations, such as roentgenograms and

6 Craig W. McK. and Walsh M. N. The Present Status of the Protruded Disk Syndrome read before the International Congress of Neurological Surgeons Copenhagen Denmark Aug. 21 1939.

Keegan and Finlayson⁷ reported that in 57.5 per cent of their cases there was from 90 to 100 per cent recovery, that in 17.5 per cent there was from 80 to 90 per cent recovery, that in 10 per cent there was 50 per cent recovery and that in 15 per cent there was no recovery. Other similar groups of cases have been reported, but as yet no reports are available concerning any large group of patients followed for several years.

The group of patients whose records we have reviewed have been followed for at least a year, and in some cases for three and four years. Many of the patients have been seen by one of us at least a year or more after the operative procedure was carried out. Those not seen at least a year later have been followed by letter. We have classified as "good" the condition of all patients who have reported that the pain for which operation was done is completely relieved and that they have returned or could return to their former work. Patients whose condition is classified as "fair" have reported improvement or that their pain is partially relieved. Patients whose condition is listed as "poor" are those for whom no improvement was secured. Results appear in tables 1 and 2. This separation into the two tables is self explanatory. In table 1 are shown the end results secured in cases in which protruded intervertebral disks were found at operation by the neurosurgeon, in table 2 are shown the results obtained in cases in which such disks were not found at exploratory operation.

We have reviewed the results of roentgenograms in all cases before operation and in most cases after operation, although in some cases late postoperative roentgenograms were not available. The various diagnoses seen in tables 1 and 2 represent condensation of a larger group of diagnoses; condensation was carried out to simplify and clarify the subject. We believe that for the purposes of this paper such condensation has not detracted from the factual data of the study. For instance, the exact situation of thinned disks is not given. In some cases the fourth lumbar disk was found to be thinned, in others the fifth lumbar disk was thinned and in still others both were thinned. The great majority of these were, in our opinion, instances of pathologic thinning rather than of anatomic thinning. We recognize the anomalous type of thin disk and also the type in which sacralization has produced a thin disk; these have not been counted as such. In the group of cases listed as "sacralization" we actually found only instances of partial sacralization. In these, union between the transverse processes and the sacrum was not solid and in most of these both a rudimentary type of disk and rudimentary facets were present, producing in many cases an unstable type of lumbosacral joint. In table 2 the list of "anomalies" includes both anomalous facets and anomalies of the bony arch, such as spina bifida and other conditions.

Recurrence of protruded intervertebral disks and recurrent symptoms arising after operation for protruded disks are listed separately (table 1), they need no explanatory comment.

OPERATION

We have used the tibial graft as a rule in these cases. In a small number of cases bone from the iliac crest was used for grafting in this series, but for the most part bone from the tibia was used. We feel that the operating time saved by the tibial graft is important.

While the neurosurgical team proceeds with laminectomy, the orthopedic team removes the required bone from the tibia. By the time the bone from the tibia has been removed and the wound closed, laminectomy usually is completed and the bed for the graft largely prepared by the neurosurgeon. The orthopedic surgeon generally finishes the preparation of the bed and places the graft. As a rule, bilateral grafts are placed across the unstable region, which usually consists of the area from the fourth lumbar arch to the second sacral arch.

Preparation of the bed is most important. The laminae and spinous processes of the area are entirely denuded of muscular and ligamentous attachment, and chips of bone are elevated from both the laminae and the spinous processes. The graft is divided into two pieces, and one is placed on each side. Cancellous bone is packed about the graft to insure its union to the host area. When a defect produced by laminectomy has been so extensive as to make it difficult to bridge the defect, a unilateral graft can be used or a double

graft can be placed on the side opposite that of the laminectomy defect. Too much care cannot be exerted in the placing of these grafts.

In these cases a minimal amount of bleeding should occur, so that postoperative hemorrhage with resultant pressure on the spinal cord will be avoided, yet it is important to scarify the lamina and spinous process of each vertebra to be sure of producing a bed to which the graft will unite. The graft must not be placed so that it can slip and cause pressure on the dura. Firm closure of the wound without drainage is important. In a very few cases, to protect the neurosurgeon's field, a drain has been used postoperatively for from twenty-four to forty-eight hours. If it is watched carefully and then removed it may do no harm, but the use of drains after bone grafting has been done usually is not desirable.

POSTOPERATIVE CARE

After the operation only a firmly applied dressing is used. Sometimes it is held in place by means of a scultetus binder. The patient is placed on a Bradford frame and turned every six hours for the first few days postoperatively. At the clinic we usually allow the patients to turn themselves by the end of a week, and the hospital period for most patients has been shortened to between three and four weeks.

7 Keegan J J and Finlayson, A J. Low Back and Sacral Pain Caused by Intervertebral Disk Herniation. *Nebraska M J* 25: 179-184 (May) 1940.

The patient is sent home with a cloth corset at the end of that time and is instructed to restrict activity. The patient may be out of bed for three hours a day for six weeks, then this time may be increased until a normal schedule has been reached. A normal schedule generally is reached by the end of three or four months after operation. At that time the patient either returns for examination or roentgenograms are sent in for inspection. If the grafts seem solidly united and strong, the patient may be permitted to return to full work. If there seems to be delay in union of the graft, the patient may be allowed a limited amount of work. It is important to be able to judge the state of the graft before decision as to the patient's return to work is reached. In the majority of cases, healing will be sufficiently advanced at four months postoperatively to permit the patient's return to work as noted previously herein, but when delay in union of the graft has occurred resumption of full activity must not be permitted. In a few cases it may be a year before the grafts are fully united and strong enough to permit the patient's resumption of full activity.

It is important to allow some degree of muscular activity as soon as the grafts are united, because this will stimulate union and ossification of the graft, and if the activity is not too violent it will do no harm. As soon as union has become strong enough, exercises designed to reestablish muscular tone and strength should be prescribed and carried out. Pain of some degree may accompany such exercises, and the patient should be warned of the possibility of it, otherwise, fear may prevent the patient's carrying out his exercises and thereby delay his return to normal activity. The belt should be discarded as soon as muscular strength has been fairly well reestablished.

COMMENT

In the tabulated material we have noted some of the contributing factors which may have played parts in our "poor" and "fair" results. It should be noted that there were no operative deaths in the series. Only 1 of the patients now is dead, and he was killed in an automobile accident months after the operation. In only 1 case did the graft become infected to such an extent that it had to be removed. In this case the achievement of fusion was questionable, and the result is only "fair." Definite psychoneurosis seemed to be an important factor influencing the "poor" results secured in 2 cases and the "fair" result obtained in

1 case. In only 3 cases did it seem to us that failure to settle satisfactorily difficulties concerned with compensation had played a part in estimation of the result. This statement can be made in spite of the fact that 29 patients of the entire group definitely were involved in compensation litigation.

In 11 cases it seemed to us that inadequate or unsatisfactory grafts played parts in the results obtained. In some the graft did not extend far enough, as in 1 case in which it was so placed as to cover an old fractured vertebra but did not reach the sacrum and bridge definite spondylolisthesis. In another case the graft bridged over the fifth lumbar and first sacral segments and failed to cover a large laminectomy defect above. In 1 or 2 cases the graft fractured. In others the grafts atrophied and partly absorbed, leaving very questionable fusion. Most of these conditions can be improved by more careful technique, and it is hoped that as experience in the combined operation is gained less difficulties from the aforementioned sources will be encountered.

Finally, it should be pointed out that many of our patients have returned not only to their former occupations but to heavy work. A summary of this is noted in table 3.

Thus it is seen that laminectomy plus fusion need not limit a patient's career as far as his work is concerned. As improvement in technique and more nearly accurate diagnosis are achieved, it is to be hoped that these figures will be further improved.

As far as we know, protruded intervertebral disks have not recurred after fusion, although this statement cannot be fully substantiated because it is possible that with more thorough study it would be found that some of our patients who obtained "poor" results might now have recurrent protruded disks. It is to be hoped, however, that by means of the combined operation the incidence of recurrence of protruded disks may be diminished.

As to this study providing any light on the question of the late changes which might arise from removal of protruded disks when fusion is not carried out, we cannot say that anything in the review of this series would lead us to advocate fusion in all cases in which protruded intervertebral disks are removed. Such an action seems unnecessary to us now.

ABSTRACT OF DISCUSSION

DR HENRY BRIGGS, East Orange, N. J. Orthopedic surgeons owe a debt to Winter and Barr, the Mayo Clinic, Springfield and others for pioneer work in this field. Dr. Ghormley has not mentioned today his own facetectomy. This was an earlier approach to the same problem and is a procedure that I predict will play an ever increasing role in the solution of backache and radiating pain as orthopedic surgeons begin to explore the pathologic conditions of the intervertebral foramen. It was pleasing to hear Dr. Ghormley say that he is fusing more and more backs following laminectomy. He is conservative in his selection of cases. I wish Dr. Ghormley would clarify his indications for the "combined operation." He tells us that 66% per cent of the cases were fused because of an associated static type of backache. It is difficult to see, for example, how one can discern by either the history or the physical examination a static type of backache in a person from whom one later removes a herniated nucleus pulposus. Orthopedic surgeons recognize as a symptom complex the so called unstable fifth lumbar vertebra. Into this classification goes that large, mysterious group of cases in which there are painful low backs and often radiating pain but not the classic neurologic findings of the herniated nucleus pulposus.

Our great interest now lies in these cases. I am beginning to feel that the pain and chronic muscle spasm of a large number of them can best be explained on the basis of an impending impingement of a lumbar nerve root. I would like to ask Dr Ghormley how he recognizes an unstable fifth lumbar vertebra at operation. I was not surprised to hear that no disk was found by the neurosurgeons in 24 cases with decreased ankle jerks. Neurosurgeons do not know how to look for them. The entire operative procedure for the treatment of a ruptured nucleus pulposus is primarily orthopedic surgery, not neurosurgery. I am amazed that the Mayo Clinic still seems to inject air or radiopaque oil in the typical case of herniated nucleus pulposus. A positive film aids little in localization and a negative plate means nothing. I agree with Dandy as to the uselessness of the procedure. I decry the use of the long tibial or iliac graft used in a strut. That type of fusion is mechanically unsound, physiologically ill conceived and technically unnecessary. The followers of Hibbs will bear me out in this statement. A chip fusion is the method of election. The latter, if desired, can be supplemented by a laterally placed spinous process plug.

DR A W ABSON, Rochester, Minn. The combined operation, as described by the authors, has a useful place in the treatment of low back and sciatic pain. The removal of a protruded disk affords relief to patients whose symptoms arise from irritation of a nerve produced by a bulging, cartilaginous mass. However, not all the symptoms may be due to the protrusion or a prolapse of the nucleus pulposus, since there may be accompanying arthritis, beginning spondylolisthesis, sacralization of the last lumbar vertebra or the existence of a long and excessively movable lumbar segment of the spinal column. When such a situation exists, neither the removal of the protruded portion of the disk nor the insertion of a bone graft in the sacro-lumbar region will suffice as a single operation. It is in this particular group that the combined operation is indicated, since the patient needs the stabilization afforded by the fusion procedures in addition to the removal of the bulging cartilaginous mass, protruded disk, responsible for the radiculitis. The question concerning the value of myelographic studies in the differential diagnosis of protruded disks has frequently been raised. In many instances the neurologic findings are sufficient to justify a diagnosis and the localization of the lesion, but more often than not the confirmatory evidence of a myelographic film is needed to support the tentative diagnosis and localization. Radiopaque oil serves as a more accurate contrasting medium than thorium dioxide sol, air or oxygen. Should it or thorium dioxide sol be used, it is well to remove it after the study or at the time of the operation. Air or oxygen as a contrasting medium has the advantage of being absorbed and not being responsible for the development of radiculitis or meningitis. To whom should the patient with low back and sciatic pain be referred? My reply would be to the orthopedic surgeon. However, should the patient present neurologic findings unexplained by osseous changes, he is then entitled to a neurologic investigation. If the diagnosis is that of a protruded intervertebral disk which has given rise to recurrent episodes of pain, operation should be recommended and performed by the surgeon best qualified to carry out the procedure. In the event of indications requiring a combined operation, it has been our practice for both orthopedic and neurologic surgeons to perform their respective parts at the same operation.

DR LEE A HADLEY, Syracuse N Y. As a radiologist I have for some time been interested in correlating the x-ray appearance of the spine with the anatomic and pathologic conditions found in the cadavers at the Medical College at Syracuse University. On dissecting a herniated nucleus, one exposes a linear fissure penetrating the posterior part of the annulus fibrosus. If, after complete removal of that hernia, dorsal extension is made on the spine, additional nuclear substance usually oozes out through the opening. I have wondered if that split should not be repaired. Patients with nerve root symptoms may have their nerve root pressure beyond the spinal canal. A spur projecting from the lateral margin of the fifth disk may encroach on the nerve to the extent of

distorting its shape and displacing it from its normal position. In the lumbar region the lumen of the spinal canal is relatively large. When one compares it with the size of the cauda equina, there is plenty of room to spare. A rather large amount of disk substance or thickened ligamentum flavum must protrude into the canal before pressure against the nerve can result. It may deflect the nerve or raise it up, but the hernia must be pretty large to press the nerve into contact with some other point of counterpressure. Hernia into the intervertebral foramen is an entirely different matter. There one has a bony ring which cannot expand. In a stained section of the fourth and fifth intervertebral foramina, the fourth foramen shows the nerve root oval with plenty of room around it for blood vessels, areolar tissue, lymphatics and fibroid tissue. That is really an encroached foramen judged by the x-ray film, but the section shows plenty of room for the nerve and other structures. In the fifth foramen, on the other hand, the disk has extruded into the constricted foramen, compressing the nerve against the posterior wall and causing it to assume a triangular shape. This is definite microscopic evidence of nerve root encroachment by a herniated disk. It seems to me that this is a problem in which herniation of disk substance into the intervertebral foramen is more important than into the spinal canal, which is relatively much larger. The operator should explore these regions laterally well out between the pedicles.

DR EDWIN W RYERSON, Chicago. Many things have been said this morning with which I disagree. With most of what Dr Ghormley and his co authors said I do agree. If there was no movement in the fourth and fifth lumbar vertebrae there wouldn't be any extruded disks in the region of the fourth and fifth lumbar vertebrae. And if in the small children who yet have to make their way in life we performed an early fusion of the fourth and fifth lumbar vertebrae to the sacrum it would be simple to prevent all the woes they have at the Mayo Clinic, taking out so many disks. Remember that when you remove a portion of a disk it impairs the disk so much that eventually the space which was formerly occupied by the disk will be flattened down and the articular space will be diminished because of the descent of the fourth lumbar on the fifth or the fifth lumbar on the sacrum. Many of these patients, as the years go by, will begin to have recurrences of symptoms, not due to the protrusion of more intervertebral disks, but because the spaces for the nerve roots will be diminished so much that they will undergo arthritic changes and will produce painful pressure on these nerves. So if we take out a disk we produce a potential future derangement which has not yet been proved in many cases. Only two weeks ago I heard a man in Chicago say that he had seen 3 cases in two weeks in which fifth lumbar disk extrusions had been removed by distinguished surgeons and in which after the lapse of a year the backs were so painful that an orthopedic surgeon had to be employed to perform a fusion operation. I think that fusion operations should be performed in all these cases of disk removal and not by the chip method, which is most unreliable, but by a combined operation with bone grafts from the tibia, and with chips from the tibia and from the laminae.

DR RALPH K GHORMLEY, Rochester, Minn. I wish we could extend this session over the week end so that all of us might comment, because there is much to be said about the problem. I couldn't deal with all the points involved, by any means. I don't agree with Dr Briggs, the neural surgeons are often our greatest friends, and there is nobody whose help I appreciate more when we are in trouble. They have helped us out of many a serious difficulty and in any case in which we are contemplating lumbosacral bone graft or fusion we ask them to see the patient and request that they decide as to whether laminectomy shall be done at the time of operation. It is true that the results of exploration may be negative, but rather than risk the patient by proceeding with a combined operation of this sort the delay occasioned by such consultation is so slight that we feel it is justified. Moreover, the neurosurgeons have been very generous to us in allowing us to decide as to whether we wish to do a bone graft in their

cases. Hence, on the whole, I think the situation is a happy one, and one that has contributed much to our knowledge of low back and sciatic pain. It is difficult in many cases to determine whether or not a patient has true static backache, but if the relief achieved by rest is complete, we usually consider the condition not to have been truly static. Many cases are very hard to analyze and to place in one category. But if we feel that the patient is experiencing sufficient distress and is of the type who might be helped by operation, we will carry out the combined operation. Dr Ryerson has more or less expressed my sentiments concerning solid grafts versus chip grafts, which is an old argument among orthopedic surgeons. As far as the question of exploration of the canal along the nerve root is concerned, I believe the operation should be done. It is being done, and the neural surgeon is doing a good job of it. For my part, I am glad to have the operation performed for me, so that I can see that the nerve is clear before grafting is carried out.

ACUTE PROTEIN DEFICIENCY (HYPOPROTEINEMIA) IN SURGICAL SHOCK

DUE TO SEVERE HEMORRHAGE AND IN BURNS,
INTESTINAL OBSTRUCTION AND GENERAL PERI-
TONITIS, WITH SPECIAL REFERENCE TO THE
USE OF PLASMA AND HYDROLIZED PROTEIN

ROBERT ELMAN, M.D.
ST. LOUIS

The war has emphasized the importance of surgical shock in such injuries as severe hemorrhage and tissue trauma and has led to many advances in its treatment. Moreover, this increased interest has thrown much light on many other related clinical conditions in civil as well as military surgery, such as burns, intestinal obstruction, strangulation and general peritonitis. Because an acute protein deficiency is shared by these various conditions, I wish to approach their therapy biochemically rather than physiologically. Moreover, this point of view has been generally neglected and leads, I believe, to much of practical value.

Acute protein deficiency is shared by these conditions because they all suffer in common from an acute loss of plasma, which is essentially a protein-containing fluid. There are several reasons why this loss of plasma protein should be studied as an acute protein deficiency rather than simply as acute hypoproteinemia. In the first place the existence and clinical detection of the deficiency by measuring the serum protein is often masked by an associated dehydration (hemoconcentration) or hyperglobulinemia.¹ Second, the loss of plasma protein undoubtedly affects other protein tissues, certainly the liver and perhaps other sites. Third, the trauma in shock is often associated with protein losses from the body as a whole as well as from the blood, as shown by the metabolic observations of Cuthbertson,² who found excessive excretion of urinary nitrogen following experimental and clinical trauma of various types. Moreover, as a general rule pathologic processes

are best viewed not from the most important tissue involved but as a phenomenon affecting the body as a whole. The concept of acute protein deficiency is justified, finally, by the additional circumstance that the body cannot correct the defect rapidly, thereby pointing to a direct and often life saving therapeutic

Fig 1—Plasma albumin is the most important fraction of the plasma proteins as far as maintaining the circulation and fluid balance is concerned, because it contributes 85 per cent of the colloidal osmotic pressure of the blood. The various factors which increase and decrease the plasma albumin are represented on the left and right respectively.

procedure, is the prompt and adequate replacement of the protein loss, wherever it may be. Figure 1 is an attempt to represent graphically the relationship between plasma protein and the factors leading to its increase or decrease. It should be mentioned that the term surgical shock in this paper will be used to describe any acute circulatory impairment which follows a sudden fall in the blood volume and is not used to describe merely the more severe impairment which precedes death.

PREVIOUS WORK

The classic investigations of surgical shock which are being continued at the present time have clearly demonstrated the existence of diminished blood volume, decreased cardiac output and fall in blood flow, all of which are the physiologic changes responsible for the circulatory deficiency and for the profound clinical manifestations. Viewed thus, the therapeutic problem is one of restoring the circulation in order to maintain the vital processes, and especially that the metabolic changes induced by the deficient blood flow may be prevented from inducing irreversible tissue damage which is the inevitable prelude to death.³

Now it is quite easy to restore the circulation in most cases of shock, the injection into the blood stream

Fig 2—A woman aged 38 whose blood pressure curve is represented above fell out of a second story window and was in shock on arrival at the Homer Phillips Hospital. Note the transient effect of saline solution and dextrose 5 per cent (A 1000 cc B 500 cc) as compared with the sustained effect of the same volume of plasma (C 1000 cc D 500 cc) in restoring blood pressure. The shaded area represents the pulse pressure. The numbers under the base line represent the time of day beginning at 4 p.m. when the patient was admitted.

early enough of an adequate volume of saline solution and dextrose will be followed by an increase in blood volume, pressure and blood flow. In mild cases this effect is sufficient and recovery eventually occurs.

Unfortunately, this simple means is insufficient in the severe cases because the beneficial effect is transient (fig 2), indeed, the temporary improvement is soon followed by a further deterioration of the already impaired circulation. The most important reason for this deleterious effect of dextrose and saline solution is the fact that such solutions possess no colloidal osmotic pressure, in other words, their osmotic pressure is due to substances of small molecular size which pass readily through the wall of the capillaries (especially when permeability is increased) and leave the blood stream soon after they are injected, carrying along plasma, thus leaving the blood poorer in plasma protein than it was before.

The conception that it is really the loss of plasma which is important in severe hemorrhage was emphasized in two important but often forgotten contributions. In 1918 Rous and Wilson⁴ showed that surgical shock following hemorrhage was not due to loss of the red cell component of the blood but to the plasma. About the same time Whipple and his co-workers⁵

Fig 3—Severe hemorrhage from a peptic ulcer in a youth aged 17 years. Compare with figure 5. The data were supplied by Dr J L Levy, Little Rock, Ark.

by plasmapheresis, a bleeding procedure which maintains the red cell volume at a normal level, showed that shock followed loss of plasma alone whenever the protein concentration was reduced sufficiently. Toward the last of World War I, the futility and even danger of using saline solution and dextrose in severe shock was known,⁶ although it was not generally realized for a decade or more after the war. For example, as late as 1936 large volumes of saline solution and dextrose were still being used in the treatment of severe burns, a lesion which shares with hemorrhage loss of plasma. On the basis of clinical studies⁷ at the St. Louis City Hospital in 1935 I became interested in the biochemical rather than the physiologic changes in these patients because we demonstrated that hypoproteinemia was an important and persistent manifestation in severe burns and that the body had no rapid way of meeting this acute protein deficiency in the plasma. Applying the obvious principle of replacement therapy, we used plasma in burns for the first time, instead of dextrose and saline solution alone. The beneficial and even dramatic effects of this form of therapy are now generally realized. It is but a step from the use of plasma in burns to its use in other conditions associated with a loss of plasma protein, e g severe hemorrhage and

tissue trauma, as well as intestinal obstruction and peritonitis. Indeed, one may say that the essential difference between plasma and simple solutions is the protein content of the former. And, since the therapeutic effectiveness of plasma is due to this difference, the fundamental concept of protein deficiency is obvious.

Fig 4—A single hemorrhage (35 per cent of the body weight of a 10 kg dog) was produced and the amount removed was immediately replaced with isotonic solution of three chlorides. Note the fall and slow return of the serum albumin concentration and even slower return of the red cells (hematocrit). The globulin fraction is not represented; it returns to normal much more rapidly (two to three days). (The hematocrit which measures red cell volume gives the same curve as the red cell count.)

PRESENT OBSERVATIONS AND COMMENT

In severe experimental hemorrhage, study of the plasma proteins revealed⁸ that, although the acute hypoproteinemia which followed was spontaneously corrected, it required days rather than hours (fig 4), obviously in severe cases hours are important, because

Fig 5—This chart and figure 3 present 2 examples of severe hemorrhage from a peptic ulcer above in a man aged 53 and in figure 3 in a youth aged 17. Note the slow regeneration of serum protein requiring ten days or more to return to normal. In this chart note the relative faster return of the total protein as compared with the albumin fraction; this is due to the more rapid regeneration of serum globulin.

the defect will become fatal unless promptly corrected. There seemed to be a paucity of clinical studies on the hypoproteinemia which follows hemorrhage, and we were therefore interested in verifying our experimental findings with observations in man (figs 3 and 5). The

cases. Hence, on the whole, I think the situation is a happy one, and one that has contributed much to our knowledge of low back and sciatic pain. It is difficult in many cases to determine whether or not a patient has true static backache, but if the relief achieved by rest is complete, we usually consider the condition not to have been truly static. Many cases are very hard to analyze and to place in one category. But if we feel that the patient is experiencing sufficient distress and is of the type who might be helped by operation, we will carry out the combined operation. Dr. Ryerson has more or less expressed my sentiments concerning solid grafts versus chip grafts, which is an old argument among orthopedic surgeons. As far as the question of exploration of the canal along the nerve root is concerned, I believe the operation should be done. It is being done, and the neural surgeon is doing a good job of it. For my part, I am glad to have the operation performed for me, so that I can see that the nerve is clear before grafting is carried out.

same slowness in the return of plasma proteins in donors giving blood for transfusions was observed recently by Ebert, Stead and Gibson⁹

In general peritonitis and intestinal obstruction, clinical study also revealed the frequent occurrence of hypoproteinemia, as shown in the accompanying table. In both of these diseases there is a loss of fluid (containing protein) in the walls of the intestines and the peritoneal cavity and thus the pathogenesis is similar to that presented by severe burns. Indeed, in many of these patients there is a high red cell count as occurs in burns, as shown in the table. There is, of course, considerable experimental and clinical evidence of the high protein content of the lost fluid in these and in traumatic conditions. This literature has been ably and recently reviewed by Harkins¹⁰ and will not be mentioned further. That such local fluid loss should lead to hypoproteinemia is not surprising, yet few such observations have been made. A striking clinical example is shown in figure 6, and other cases are listed in the table.

Loss of plasma in burns, intestinal obstruction and peritonitis extends over hours and days unlike the sudden loss in severe hemorrhage and thus the hypo-

Fig 6—These curves of the red cell count and serum albumin concentration were observed in a 6 year old child who seven days after appendectomy had a hemoconcentration and low serum albumin coincidentally with abdominal distention and other signs of intestinal obstruction. Despite the large parenteral fluid intake she passed no urine and her general condition was critical. Following the administration of three large plasma transfusions the clinical improvement was dramatic and the recovery uneventful including the disappearance of the distention. Note the rise in the serum albumin and the fall in the red cell count. The globulin fraction remained unchanged and is not shown. This is case 13 shown in the table.

proteinemia is associated less with surgical shock and more with disturbances in fluid balance and dehydration. Moreover, since the fall in blood volume in these conditions does not include loss of red cells, there is apt to be a hemoconcentration, unlike hemorrhage in which there is apt to be a hemodilution. Nevertheless the important feature in common is the fall in serum protein and thus the concept of acute protein deficiency due to loss of plasma. Regardless of clinical manifestations the concept of protein deficiency, particularly as it affects the plasma, leads to the use of true replacement therapy, for it emphasizes the need for correcting the acute hypoproteinemia with protein promptly and with enough protein to correct the deficiency. As far as the blood is concerned, the most direct replacement is, of course, that with plasma itself, but its dramatic effectiveness is often missed unless enough is given. For example, most physicians will not hesitate to give a patient 2 to 3 liters of saline

solution and dextrose yet will use but 250 cc of plasma. As I¹¹ have pointed out before, 1 or 2 liters a day of plasma may be needed in severe burns to overcome protein deficiency in the plasma, and similar amounts will be necessary in other cases. Indeed, it is not at all unusual to have to give in the course of a day or two an amount of plasma which equals or even exceeds the patient's total plasma volume (roughly 3,000 cc) in order to reduce the hemoconcentration, maintain the circulation and reestablish the fluid balance.

How can the physician tell how much plasma the patient needs? Following an ordinary severe trauma or hemorrhage there is usually little difficulty in answering this question, for the deficiency is due to a single loss, in most adults a liter of plasma or 2 liters of whole blood is a good initial dose, though more may be required later. When the deficiency is due to a burn, intestinal obstruction or general peritonitis, it is less easy to estimate the amount required because the loss of protein extends over several hours or days. Indeed, it is probably because of this time element that disturbances in fluid balance become important in the clinical picture of these three conditions. Thus, as well as increases in the red cell count, offer a much better clinical measure of hypoproteinemia particularly because inferences from the determination of serum protein are apt to be deceptive, owing to associated dehydration. In other words, frequent red cell counts and accurate estimations of the twenty-four hour intake and output, especially the amount of urine excreted are of great diagnostic value. In general, severe serum protein deficiency is not present or is being corrected spontaneously when the adequate administration of saline solution and dextrose alone leads to a fall in the red cell count which stays down especially when a good diuresis is produced, thus indicating that normal fluid balance is being reestablished. The importance of fluid balance for surgical patients has been so well studied and emphasized by Coller and Maddock¹² that it will not be discussed here. However, it must be emphasized that fluid balance cannot be achieved if there is a severe protein deficiency, because fluid interchange through the capillaries takes a "one way" turn because the colloidal osmotic pressure of the blood falls as already mentioned, whenever the plasma protein is reduced. In following fluid balance it should be remembered that there is usually an insensible loss of 2,000 cc a day, which must be taken into account in estimating the intake. Ordinarily a diuresis of 1,000 cc or more with an intake of 3,000 cc is a good indication of normal fluid balance. The following recent experience is a simple example of the value of the red cell count and urinary output in indicating the correction of protein deficiency with a large plasma transfusion.

The patient was a 12 year old boy on whom I operated twelve hours after the onset of acute abdominal symptoms, and relieved a tremendous strangulation of the small intestine due to a fibrous band. The next day in spite of adequate saline solution and dextrose he passed no urine and his red cell count was 623 million. The general condition was poor. He was given 500 cc of plasma (10 cc per kilogram of body weight) and within twelve hours he had passed 600 cc of urine and his red cell count fell to 410 million, where it remained till his recovery.

Other examples will be found by consulting the table, especially case 13, which is also represented in figure 6. In cases 9, 10 and 11 correction of the hemoconcentration followed the injection of amino acids (amigen) and in case 12 the injection of amigen was followed by a striking correction of the hypoproteinemia.

To prepare large amounts of human plasma will always present a considerable practical problem because for each liter four donors must be bled. For this reason plasma substitutes such as acacia, gelatin and pectin have been tried, they all have in common a high colloidal osmotic pressure, i. e. they exist in solution as particles of large size and thus are valuable because they simulate thereby protein behavior. Being foreign

the building stones of protein for all tissues of the body it is important to emphasize by contrast that plasma is able to correct directly only hypoproteinemia. Because each body protein has a different amino acid composition, plasma protein must first be hydrolyzed by the body and then resynthesized before it can be used outside the blood stream.

Previous studies from this laboratory and clinic¹³ have already shown that the intravenous injection of an amino acid mixture prepared by the enzymic hydrolysis of casein (amigen) is well utilized by the body and leads to the synthesis of plasma protein in chronic hypoproteinemia of dietary origin. I have also reported experiments¹⁴ which showed definite increases in the

Hypoproteinemia in Patients with Intestinal Obstruction and Peritonitis

† Amigen is the trade name for the amino acid mixture used on these patients. It is an enzymic hydrolysate of casein.

substances, however, they are disposed of by the body more or less effectively in one way or another. They cannot really correct protein deficiency but merely supply one of the important properties of protein. Animal plasma would solve somewhat the problem of practical availability, but because of protein sensitivity (allergy, anaphylaxis) has not been safe to use.

An entirely new approach to the problem of correcting protein deficiency parenterally is the use of the building stones of protein, i. e. amino acids or small aggregates thereof—polypeptides. In acute conditions this form of therapy is based on the assumption that these building stones may rapidly be built up by the body into true plasma protein, an assumption which is supported by much recent evidence. In general, the use of amino acids for the correction of protein deficiency parenterally is just as convenient as the injection of dextrose and saline solution, moreover, they supply

low serum protein following acute hemorrhage by this means. In the table are listed several clinical trials with intravenous amino acids on patients with intestinal obstruction and general peritonitis. The injections were followed by excellent clinical results, as shown by improvement in the general condition, relief of hemoconcentration and sometimes by actual increases in the concentration of serum protein.

These preliminary observations are now being followed up with more detailed studies. Especially impor-

tant in the acute conditions discussed herein is the speed with which synthesis of serum albumin can be made to occur. Only by rapid correction of the protein deficiency can many of the manifestations of surgical shock be sufficiently improved to prevent those irreversible tissue changes, especially in the central nervous system, which lead inevitably to death.

SUMMARY

Acute protein deficiency is a decisive but hitherto unemphasized factor in the pathogenesis of surgical shock and other clinical manifestations, shared in common by severe hemorrhage, burns, intestinal obstruction and general peritonitis. Hypoproteinemia confined largely to the albumin fraction is but one aspect of this deficiency, although it may be masked by dehydration. This protein defect in severe cases cannot be corrected rapidly enough by the body and therefore requires prompt and adequate replacement therapy. Because of its protein content, plasma is effective if given early and in large enough amounts. The building stones of protein (amino acids) offer another way of meeting protein deficiency. This new method of therapy has already been shown to correct chronic hypoproteinemia of nutritional origin, early trials in acute hypoproteinemia have yielded promising results.

ABSTRACT OF DISCUSSION

DR ALEXANDER BRUNSWIG, Chicago. Recently there has been a great deal of interest in the protein metabolism of the surgical patient. At the close of the last war, shock was treated by the injection of acacia and other solutions which had an osmotic pressure. Little thought was given to their possible nutritive properties because it was felt that if the shock could be weathered the question of nutrition could be dealt with later. In the main that still applies. Our knowledge of protein metabolism has been extended since then and there is a possibility that even a brief definite protein deficiency may tip the balance one way or another. We see patients die suddenly with advanced cancer, apparently there was not much difference in amount of malignant tissue in the body at the moment of death and a day or two previously. Necropsy fails to reveal the cause of death. It is conceivable that such sudden deaths and in other instances sudden collapses right after operation in patients who are already undernourished might be connected with some acute protein deficiency. The use of plasma is the best method for rapid correction of acute plasma protein deficiency. I believe that surgeons do not always give enough plasma or blood when there is a clearcut indication for such replacements. A transfusion of 500 or 600 cc (that quantity seems to have been finally regarded as a standard, why it should be 500 or 600 cc and why it isn't 400 or 700 or 800 I don't know) seems to assure the surgeon that he has done a great deal. He has done something, but often it may not be enough. If the use of larger quantities of plasma and blood obtains, the operability of intra-abdominal neoplasms especially can be considerably extended. I have used as much as 1,500 cc of plasma and 3,000 cc of blood in the course of three to four hours during extensive operations for intra-abdominal neoplasms. Recently in the removal of a tumor diagnosed two and a half years previously as a carcinoma of the left adrenal but which grew locally in size and had not metastasized there was infiltration of the posterior abdominal wall and the large lumbar veins were gaping and bleeding, for a time it wasn't possible to arrest this hemorrhage. In this case 2,000 cc of plasma and 2,500 cc of blood were used in about two and a half hours. At no time did the patient's blood pressure fall below 120 nor was there evidence of profound shock. I believe that that was due to unrestrained transfusion of plasma and blood. All gross evidence of tumor had been removed and at present the patient, a man aged 38 is back at work.

DR H. N. HARRIS, Detroit. I wish to confine my discussion to the acute protein deficiency of burns. The first clinical use of plasma in burn cases was reported by Dr. Elman in 1936. The plasma therapy of burns is one of the most important advances in the general therapy of this condition. I wish to describe a way of graphing the course of a burned patient that I have found useful in demonstrating the importance of the protein deficiency. The top portion of the chart shows the changes in the hematocrit over a period of five days, showing the very high hematocrit, a few hours after admission, of 73. Later, with plasma, the hematocrit came down and on the fourth and fifth days was actually below the normal value. This secondary anemia has been found in many burn cases. The lower portion of the chart shows the amount of plasma protein given in grams at various intervals. This particular patient received doses of plasma of 4,400 cc in the first thirty hours after the burn. The middle portion of the chart is the one to which I wish to draw special attention. The plasma protein change in grams per hour is calculated from the plasma deficiency plus the plasma that has been given, so this is the net plasma protein loss in grams per hour. The plasma deficiency is calculated from my own formula, namely that in a burn case 100 cc of plasma is needed for each point for which the hematocrit exceeds the normal of 45. Thus if the hematocrit is 73 at this point the patient needs 2,800 cc of plasma. In following this graph, one can see that at the first reading the patient was losing plasma protein at the rate of 44 Gm per hour. Later the loss was 16 Gm per hour, and then on the third day the neutral point was reached, indicating that the capillaries had regained their normal permeability. This rapid loss of 44 Gm per hour is especially important when one notes that the patient was calculated to have in his entire blood plasma only 208 Gm of plasma protein. With this rapid loss of 44 Gm an hour the patient could not go long before he might lose a large proportion of all the plasma protein he had. These charts demonstrate two points: (1) the early rapidity of the loss of plasma protein, which indicates the necessity for prompt treatment if the patient's life is to be saved in severe cases, (2) a point which has already been emphasized by Dr. Elman and by Dr. Brunswig, that large doses of plasma or of plasma protein are necessary for restoration. It is no more logical always to give a burned patient a pint of plasma than always to give a diabetic patient only 10 units of insulin. The plasma dosage should be chosen to fit the patient.

DR ROBERT ELMAN, St. Louis. Since there are various types of protein hydrolysates which may be available for intravenous injections, I should like to put on record what I think are four criteria for their use. 1. These hydrolysates must be prepared from complete proteins and contain all the essential amino acids. 2. The method of hydrolysis should be such as to lead to a product which contains enough of all these essential amino acids. 3. When supplied as the sole source of nitrogen, the product must satisfy each of the following three biologic needs: (a) produce satisfactory growth in young animals, (b) result in positive nitrogen balance and (c) achieve serum albumin regeneration in depleted animals as a result of protein deficient diets. 4. When used intravenously they produce no anaphylactic or other untoward reaction.

Venereal Disease and Open Prostitution.—For the eighteen month period prior to the closing of the houses [of prostitution] a total of 358 gonorrhea cases were admitted to the Vancouver (British Columbia) Clinic. For the eighteen month period following the closing there were only 100. For the eighteen months during which the houses were open 88 of these cases originated in houses of prostitution and 270 originated outside such houses. For the eighteen months following the closing, only 12 cases originated with professional prostitutes. But note this. The number of cases originating outside houses of prostitution also dropped—from 270 to 88. Thus, even clandestine contacts and their attendant infections decreased in the community following the closing of the houses of prostitution.—Broughton, P. S. *Prostitution and the War*, Public Affairs Pamphlet No. 65, Public Affairs Committee Inc., New York, 1942.

BRONCHOSCOPY IN THE DIAGNOSIS
AND TREATMENT OF BRONCHIECTASIS IN CHILDREND E S WISHART, M.D.
TORONTO

Bronchography for the purpose of demonstrating the location and severity of bronchiectatic lesions was first used at the Hospital for Sick Children, Toronto, in December 1927. Difficulties were encountered, but these were overcome cautiously and gradually. The accepted procedure as now provided weekly by the ear, nose and throat service is submitted as a contribution in the refinements of the treatment of bronchiectasis in children.

It is our practice to put iodized oil into the lungs by means of the bronchoscope under general anesthesia. This has been of great value in diagnosis, and the recognition of this has had important results. The diagnosis in great numbers of suspected cases has been determined and thus clinical diagnosis has been improved. Bronchiectasis now is frequently diagnosed, and the number of cases that are labeled either chronic bronchitis or unresolved bronchopneumonia has become proportionately less.

In the last thirteen years 433 cases have been diagnosed as bronchiectasis and 1,015 records of these cases are here studied. I have the authority to state that the medical, surgical, pathologic, bacteriologic, radiologic and anesthetic aspects of this study have been read and confirmed by the department responsible. The heads of these departments and the members of their staffs have assisted in the preparation of this report, particularly Dr Gladys Boyd, who has medical charge of the bronchiectatic cases.

THE MEDIUM USED

Iodized poppyseed oil was used from the commencement but other oils also have been experimented with. My associates and I found by various experiments that it was a mistake to use too thin an oil. At one period iodized poppyseed oil could not be obtained and iodized vegetable oil was substituted. The results were fairly good but the solution had the disadvantage of spoiling readily and thus becoming a worry to those who were using it. Iodized poppyseed oil is now manufactured on this continent and is again being used. All the illustrations were made with this oil.

TYPE OF CASE

Children of every age, as shown in the accompanying table, from infancy upward and with the severest types of bronchiectasis have been investigated and treated. Patients are sent to us who previously would have been considered very poor anesthetic risks. Bronchoscopy is done on them because the medical service is convinced that the procedure is of such benefit to the patient that the risk must be taken. The child who is now physically our greatest triumph originally had suction applied when he had a temperature of 106 F and was exuding extremely thick pus. During the poliomyelitis epidemic 1 severely ill bronchiectatic

patient was treated while in the Drinker respirator. This boy is well and has not required suction for several years. Bronchography has been done on patients under 2 years of age and suction on patients under 1 year of age without any complication.

The great majority of children are admitted the afternoon of the day before and discharged the day after injection of iodized oil.

PREPARATION OF THE PATIENT

In the early years of our work sedatives were given before operation. We gradually learned that better results were obtained when they were withheld. Now a sedative is omitted because the success of the procedure, as will be apparent, depends in part on an active cough reflex.

METHOD OF BRONCHOGRAPHY

The patient is placed on the table on his side with the diseased lung dependent. This position is of assistance to the anesthetist, for during the induction of anesthesia the patient's cough reflex is stimulated and quantities of secreted fluid are coughed out. The induc-

tion is continued until an anesthesia is reached deep enough to allow the introduction of the bronchoscope without any damage to the patient or embarrassment to the bronchoscopist. Then the patient is turned on his back and the bronchoscope inserted.

A suction tube through the bronchoscope is used to clear the trachea and the main bronchi. The anesthetic (ether vaporized by a current of oxygen) is continued through a rubber tube attached to the anesthetic arm of the bronchoscope. Now the depth of anesthesia is diminished to permit deeper respiration and cough. This favors the expulsion of exudate from the distal portions of the bronchial tree. The surgeon draws this away as it appears. Gradually the bronchi become clearer and clearer and eventually he inserts the bronchoscope as far down each main tree as he considers it safe and advisable and aspirates through a suction tube the material he finds.

When no more material is being coughed out of the bronchial tree the anesthetist increases the depth of anesthesia to the degree which he considers advisable for bronchography. This process is accelerated by heating the ether vapor with hot water. The surgeon can further hasten the performance by occasionally putting his thumb over the proximal end of the bronchoscope during inspiration and taking it off during expi-

From the Department of Otolaryngology and from the Department of Pediatrics of the University of Toronto Faculty of Medicine and the Hospital for Sick Children.

Read before the joint session of the Section on Laryngology, Otolaryngology and Rhinology and the Section on Pediatrics at the Ninety Third Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1942.

ration. He will do this in cooperation with the anesthetist and act according to the latter's wishes. When the coughing has stopped and all visible exudate has been removed, the patient is ready for the injection of the iodized poppyseed oil.

Failure to have removed the exudate will result in poor filling of the bronchi.

Fig. 1—Frame carrying a stretched canvas which placed on the primary X-ray table greatly facilitates bronchography.

The depth of anesthesia now reached must last from three to five minutes. The suction tube is removed. The room is darkened and the radiologist, placing the fluoroscopic screen above the patient's chest, notes the position of the distal end of the bronchoscope, which is pulled back or advanced as he desires. The tube is inserted until it is seen just to project beyond the end of the bronchoscope. Iodized oil is then injected by the surgeon's assistant through a syringe, which has a special nozzle that locks into the tube. The injection is done slowly and steadily. Burrell's syringe or some modification of it is excellent for the purpose, as with it the speed of the injection is under control at all times and no oil escapes to embarrass the operator.

The oil is introduced into the part of the bronchial tree specified by the medical service. Injection of the right or the left lower lobe is usually requested. The adequate injection of the upper lobe is fraught with great difficulty. The injection of the right middle lobe is not so difficult but also requires a special procedure.

Fig. 2—Another view of the frame. Plates or films can be placed under the patient and removed freely without any disturbance of the patient.

The word injection has been used, but the term is a poor one. The iodized oil is ejected from the syringe by controlled force but should find its way gently out of the end of the tube into the bronchus. Inspiration by the patient carries the oil from the main bronchus to the smaller bronchi and from there into the bronchioles. These parts fill only if sufficiently clear of secretion and if this part of the lung expands with inspiration. In extreme bronchiectasis the tissues are

fibrosed and the affected lobe no longer expands with inspiration; consequently the cavities must fill by gravity and gentle pressure. It is an absolute mistake to inject the iodized oil forcibly into any part of the bronchial tree.

The mere introduction of iodized oil into the bronchial tree is not sufficient. The oil must reach the diseased portions of the bronchi in sufficient quantity and remain there long enough to enable the radiologist to make the necessary exposure.

During this procedure the radiologist is watching the fluoroscope and, when he notices that sufficient iodized oil has been put in to fill the area desired, the injection is stopped.

The fluoroscope is removed, the room lights are turned on and the bronchoscope is pulled back into the trachea. Two anteroposterior roentgenograms are taken. Then the bronchoscope is removed. The patient is turned on the side with the injected lung downward and two lateral films are taken. The earlier roentgenograms are more likely to be perfect than the later ones owing to the lightness of the anesthetic. As the effect of the anesthetic passes off the patient tends to cough and also to breathe more quickly, hence it is important that the facilities should permit pictures to be taken as rapidly as possible.

Figures 1 and 2 show the apparatus designed by Dr. A. H. Rolph, radiologist to the hospital, for use in this work. The sympathetic cooperation of all who are concerned is required for success. Obviously bronchography on some patients is relatively easy and on others desperately hard. This makes the timing, cooperation and team-play all the more important. The surgeon must not commence the injection until the anesthetist signifies readiness. The anesthetist must maintain the anesthesia for the time required. The radiologist must make his exposures and consequent changes of film with the least possible delay.

INFORMATION OBTAINED

In 230 of the proved cases bronchiectasis was demonstrated on the right side only in 72 cases, on the left side only in 98 cases and on both sides in 60 cases. With the 3 exceptions noted elsewhere, iodized oil had been injected into the side suspected to be normal before major surgery on the grossly diseased side had been permitted. Information regarding all the lobes of both sides had been obtained prior to resorting to major surgery.

Bronchoscopy in some instances has confirmed the clinical observation that the disease was hopelessly severe. Certain of these have progressed to a fatal termination. Some undoubtedly had their lives prolonged by bronchoscopic suction.

COMPLICATIONS AND ERRORS

In the early years of this work laryngeal edema frequently followed. Now it rarely occurs except in babies, for we have learned to make it a rule to use a bronchoscope which is relatively small for the patient. We never use a size larger than 5 mm. in diameter.

The total number of embarrassing complications following 1,275 injections of iodized oil or suction in cases of bronchiectasis was 7. These consisted of laryngeal reactions sufficient to cause severe embarrassment in 4 cases and to require tracheotomy in 3. Only one death that can be ascribed to injection of iodized

oil occurred in the entire series. It happened in the early years of this work. After the injection the girl, aged 8½ years, required tracheotomy, from which she recovered. The oil liquefied the pus and the quantity of the latter increased so greatly that it became impossible to remove it by suction. When we suspect that a patient is so loaded with bronchiectatic secretion we no longer advise bronchography. Instead, the patient is first subjected to a long period of postural drainage during which suction drainage is occasionally performed under anesthesia.

Some patients have so much thick pus that a good picture cannot be obtained.

Nearly all these complications occurred in the first few years of our work. Experience has shown how they may be avoided. Our record of 1,268 injections and suction without serious embarrassment is proof that information for the medical and surgical services is being obtained with only slight risk to the patient.

The hazard of any bronchoscopy is greatly increased by a previous but recent bronchoscopy by unskilled hands. When such has occurred it is wise to postpone

TALLACY TO BE AVOIDED

Of 433 cases in which bronchiectasis was diagnosed clinically, 230 have been confirmed by iodized poppyseed oil. In 88 iodized oil was not injected. In 115 the diagnosis was not confirmed by iodized oil. But this does not mean that the clinical diagnosis was incorrect.

In many of the cases not proved by a contrast medium, bronchoscopy revealed a localized lesion in the bronchial tree or disclosed hemorrhage and thus confirmed the clinical diagnosis.

The absence of evidence by contrast medium of dilatation in a lung clinically bronchiectatic does not in itself rule out bronchiectasis of considerable extent. Three roentgenograms of the same patient illustrate this point (fig 3). The first (A) demonstrates slight but definite cylindric dilatation, the second film (B) shows practically no cylindric dilatation, but in the third (C) my colleague Dr. Strachan successfully demonstrated by injection of iodized poppyseed oil still more cylindric dilatation than was originally shown. These x-ray views were taken of a patient with clinically stationary bronchiectasis.

Fig 3—Bronchograms of a patient with clinically stationary bronchiectasis.

bronchoscopy for at least four days to allow for possible traumatic edema to subside.

Overfilling of any part of the lung renders the roentgenogram useless for visualization. It may be caused by putting the tube containing the oil tightly into a bronchus. This error may be avoided by following the directions already given. It may be caused by injecting the oil too rapidly. The speed of injection should be regulated by the radiologist as he watches the fluoroscope. Overfilling may be caused by continuing the injection after the radiologist has signified that there is enough injected for his purpose.

If the team play has been good an active cough reflex will be returning directly after the last roentgen exposure has been made. The patient is now lying on the side into which the iodized oil has been injected and suction of the throat is used to aspirate what is coughed up.

The iodized oil remains in the bronchial tree for various lengths of time. Patients with a loose cough empty themselves quickly. Patients with no cough often retain the iodized oil for two to three weeks. Patients with a normal bronchial tree may retain small amounts for many months.

cally stationary bronchiectasis. They do not indicate that the patient improved and then got worse again. They do not indicate that the size of the cavities changed. They show that cavities which are inadequately emptied will fill incompletely with iodized oil. They are presented to indicate that if the pus is extremely thick or if the surgeon does not take adequate pains the presence of bronchiectasis may not be shown.

After bronchography it is occasionally possible to state categorically that a bronchial tree is normal. Inadequate visualization of any part prevents such assertion. The criterion is normal filling with normal outline. The delicate tracery of the normal bronchial tree is beautiful and unmistakable.

The absence of iodized oil in any part is an indication that the part may be abnormal. An abrupt blocking of a bronchus demands investigation of the area that lies beyond. Abnormality of outline is an indication of abnormality but does not prove that such picture is the complete picture of the abnormal area. This point has been demonstrated over and over again in our work and is the excuse for my providing another illustration.

The accredited literature contains a report of an extreme degree of bronchiectasis developing in an adult in six weeks, which I believe is an erroneous conclusion arising from neglect of this very point. I believe that had investigation been performed by the method we advise and with the care we urge the presence of bilateral basal bronchiectasis would have been demonstrated before the lobectomy.

Three roentgenograms (fig. 4) are shown of a boy aged 6 years with clinical signs of chronic bronchiectasis. At the first bronchography a great quantity of purulent material was coughed up and a considerable quantity was sucked out before *A* was made, but it was obviously not a satisfactory picture. For the next two months postural drainage was instituted.

At the second operation the same surgeon took more care to aspirate the bronchial secretion before he injected iodized oil. The result (*B*) was the demonstration of cavities very much larger than those originally portrayed, but again the medical service was not satisfied with the picture.

On the third occasion, the anesthetist and a different surgeon, profiting by the two previous trials, took still

SURGERY

Major surgery has accounted for all the cases listed as cured. The operative technic has improved so much from the early years that the mortality rate which was high has now become almost nil. In the last ten years only one fatality has followed lobectomy and/or pneumonectomy.

SINUSITIS

I had hoped to make statements supported by figures regarding the relationship of bronchiectasis and sinusitis. The diagnosis and its recognition and the success of treatment of sinusitis vary with the clinician, and agreement regarding the results is almost impossible to obtain.

It has been deemed wise, therefore, only to make statements regarding the relationship which meet the general agreement of the services involved.

Many of our series had infections of the upper respiratory tract from early infancy—and for these it is possible to argue that the infection antedated the bronchiectasis and, therefore, may have been a cause. In many histories frequent head colds were denied.

Fig. 4—Bronchograms of a boy with clinical signs of chronic bronchiectasis

greater pains. Suction was continued for twenty minutes or more. The result was a much truer picture (*C*) of the condition of the left lower lobe.

This series has been shown to demonstrate that bronchography requires cooperation between all services in order that a true picture of the condition may be obtained. It also shows that as the result of time and injection of a contrast medium the diseased cavities of the bronchi had become much cleaner.

We have never observed—apart from the accidental inhalation of a foreign body or following an attack of whooping cough or bronchopneumonia—undoubted bronchiectasis subsequently portrayed in a lung previously undeniably normal, but we have seen it eventually demonstrated in cases in which the early contrast medium pictures could be considered possibly but not definitely normal.

CONTRAINDICATIONS

Babies under 1 year of age and all bronchiectatic children with local bleeding areas are, with rare exceptions, unsuited for bronchography. Three patients had bronchiectasis confirmed by lobectomy; iodized oil was not injected because of the local condition found in the bronchial mucosa by bronchoscopy.

(By far the most frequently recurring statement was that the patient's cough had originated with an attack of whooping cough or pneumonia.) We have no evidence from autopsy material to show that sinusitis has been present in even a small percentage of the bronchiectatic patients.

In the preparation of this paper many cases suspected of being bronchiectasis have had to be eliminated because the subsequent records have shown that they were cases of bronchitis associated with infections of the upper respiratory tract and that cure or alleviation has depended on the success or otherwise of the treatment of those infections.

Out of 433 patients only 84 have been reasonably proved to have sinusitis of any degree—an incidence of 19 per cent. The ultraconservative would make this percentage smaller. On the other hand, the medical service believes that many patients in this series have had sinus treatment in the outpatient clinic and that the percentage that has been quoted is far too small. The medical service insists that clinical cure of certain severe bronchiectatic children was not achieved until their maxillary sinusitis had been improved by radical operation.

Our early policy was to postpone ear, nose and throat consultation until after the demonstration of bronchiectasis by bronchography, but now that we know that treatment of any sort (short of major surgery) does not remove or diminish the size of the bronchiectatic lesions, our policy has changed. We now consider ear, nose and throat consultation an essential part of the initial examination of a bronchiectatic patient.

FOREIGN BODIES

In 15 of the 230 cases proved by bronchography, the bronchiectasis followed the inhalation of a foreign body 6 into the right and 9 into the left bronchial tree. Several of the foreign bodies were unsuspected—a timothy top, a tooth, an apple seed and the rubber from a pencil, a second timothy top in an abscess pocket close to the pleura was discovered after lobectomy. Unsuspected foreign bodies are sufficiently frequent to make bronchoscopic examination imperative in every case of bronchiectasis.

PATHOLOGY

Material for the study of bronchiectasis has been obtained from 41 cases, 18 surgical and 23 autopsy specimens. Studies of a portion of this material have already been reported by Erb,¹ the hospital pathologist. The typical lesion in chronic bronchiectasis is a series of dilated tubes or sacs traversed irregularly by ridges or folds so that the true lumen of the bronchus or bronchiole is its narrowest portion. This helps to explain the difficulty in draining bronchiectatic secretions. Bronchi thus diseased vary in size from minute dilatations to huge sacs and may have shapes variously described as cylindric, varicose, globular and fusiform.

The primary lesion is an infection of the bronchial wall with ulceration of epithelium and destructive changes extending into the supporting structures with subsequent dilatation. When these changes occur in the larger bronchi they can be seen through the bronchoscope. Lesions such as these may develop quickly after occlusion of a bronchus by a plug of secretion or by a foreign body.

Bronchiectasis in an atelectatic lobe with a triangular basal roentgen shadow injected with iodized oil has been reported and discussed by Boyd.² A history of hemoptysis was obtained in only 21 instances. The distribution of the lesions demonstrated has already been mentioned.

BACTERIOLOGY

A small light bottle inserted in the suction apparatus close to the suction tube has been used in about half the cases to collect a specimen of the material in the bronchi. The character and quantity of the bronchial secretions coughed up or aspirated during the bronchoscopy are valuable evidence of the state of the lesions. Examination consists in estimation of the amount of this material coughed up during induction and that suctioned, the direct smear is searched for pus and bacteria, and twenty-four and forty-eight hour cultures are made to determine the organisms present.

The results of the cultures are as follows: hemolytic streptococcus 306, "mixture" of organisms 292, Streptococcus viridans 192, Staphylococcus aureus 128, Bacillus influenzae 126, pneumococcus 62.

Bronchial stenosis from pressure by tuberculous glands caused the bronchiectasis in 3 cases.

Specific bacteria have not been found. In the majority, not only was the infection mixed but the flora varied from time to time in the same patient. Our conclusions are still the same as reported by Erb.¹ "The bacteriology of bronchiectasis is the bacteriology not of the chronic bronchiectatic lung but of the bronchopneumonia or other acute respiratory disease which marked the onset of symptoms."

MORTALITY

In the series of 433 cases of bronchiectasis studied there were 29 deaths. Sixteen of these were of babies with an overwhelming infection (in 13 of them bronchoscopic studies were not made) and bronchiectasis was a postmortem finding. One case was ascribed to our diagnostic procedure. Five followed lobectomy at longer or shorter periods about ten years ago. In the remainder there was such advanced disease that treatment was of no avail.

TREATMENT

The treatment of bronchiectasis in this hospital has been reported by Boyd.³ Only points germane to this paper are dealt with here.

A patient with bronchiectasis is prone to suffer from repeated reinfections of his bronchiectatic lesions and from repeated attacks of aspiration bronchopneumonia. Control of infection in the sinuses is indicated. Drainage of the bronchial tree must be maintained until ulceration is healed. When the bronchial mucosa becomes reinfected suction must be used as often as necessary in conjunction with postural drainage until the infection is again eradicated. Each case is a law unto itself.

In some instances these measures produce such freedom from symptoms that the parents will neglect or even refuse to bring the child for examination. Of the patients Dr. Boyd has been able to follow she estimates that 41 per cent are worse, 80 per cent are improved and 44 per cent are cured.

Only those patients who have had the diseased lung removed surgically have been listed as cured. But many patients considered improved are clinically cured, that is, they are symptom free and the parents are pleased to feel that there is no necessity to bring the child to the hospital for observation.

Surgical removal of the diseased lung offers the only cure in cases of advanced bronchiectasis.

Bronchography plays a great part in the proper selection of cases suitable for lobectomy. The bronchial tree must be mapped accurately, since cases presenting bilateral lesions are absolutely unsuitable and pneumonectomy rather than lobectomy is required if the whole lung is diseased.

The condition of the bronchial tree must be known before operation is arranged. Lobectomy is contraindicated when the bronchial tree presents active ulcerations and granulations. Only bronchoscopy can give the necessary information. The surgeon desires to know that the patient has the minimum amount of septic material in his lung. Only bronchial suction shortly before he plans to operate can give him this knowledge.

IODIZED OIL IN TREATMENT

In a certain percentage better emptying is obtained when iodized oil is injected at the time of suction, and the patient can then go for a longer period between suction. The statement is frequently heard that the child does better after treatment on Tuesday (the day iodized oil is injected)* than when done on one of the other days of the week (when only suction is performed).

CONCLUSION

We believe that bronchoscopy, together with bronchoscopic suction, injection of iodized oil under general anesthesia and bronchography has proved of unquestioned benefit in the study and treatment of bronchiectasis in children. These procedures determine which children are suitable for the only cure known—major surgery. These preliminary studies disclose the cases in which major surgery is contraindicated. The degree of the existing disease is ascertained. Bronchoscopy provides the most effective form of treatment of the large group which does not require major surgery. Bronchography permits the early definite diagnosis of the disease and, therefore, affords the great hope that the further progress of a most devastating disease can be checked.

170 St. George Street

ABSTRACT OF DISCUSSION

DR. LOUIS H. CLERF, Philadelphia. I wish to compliment Dr. Wishart on his presentation. I believe we are agreed that the frequency of bronchiectasis is not too well recognized by the medical profession and that it is a serious condition, with high morbidity and mortality rates. I have been viewing these cases from the standpoint of the bronchoscopist, and I can certify to what Dr. Wishart has said, namely that bronchoscopy is not a serious procedure either as a diagnostic or as a therapeutic aid in children. Further, the instillation of iodized oil for diagnosis is a safe procedure in spite of an occasional untoward effect. The use of iodized oil is after all an absolute necessity in diagnosis. One can make a diagnosis of advanced bronchiectasis by bronchoscopy, by roentgen examination or on the clinical findings alone. The difficulties are greater in the early case. It is the early case in which we are particularly interested, since it is in this case that successful therapy can be instituted. The question of anesthesia, local or general, and the employment of a sedative is a personal problem. I use local anesthesia with sedation. The important factor is to use iodized oil for diagnostic purposes to ascertain if bronchiectasis is present, to determine its extent and degree so that surgical treatment may be carried out. This is the only method of therapy that offers anything in these cases. An occasional patient has recovered from bronchiectasis after conservative medical therapy but for a majority of them the prognosis is not good without surgical treatment.

DR. D. E. STAUNTON WISHART, Toronto. I want to assure Dr. Clerf that before any major surgery is attempted, not merely the diseased lobe is mapped, but all the other lobes of the lung are ripped. In making a synopsis of my paper for presentation this morning, that was one of the points I had to leave out. One of the members has asked how much iodized oil is used. I use about 15 cc. on the average child. I want you too to appreciate that we are working on children, not adults, and if you noticed the table, the great mass of the children are under 7 years of age. Our medical and surgical services desire exact information regarding these little people. I sincerely believe that I am offering something in suggesting that the work be done under general anesthesia.

INTER-AMERICAN MEDICAL
RELATIONSHIPS

MORRIS FISHBEIN, M.D.

Editor of The Journal of the American Medical Association
and of Hygieia, the Health Magazine

CHICAGO

In its development throughout the world, medicine has passed through innumerable transitions from country to country, from subject to subject, from leader to leader. The reasons for such continuous transition have been perhaps largely economic but no doubt also spiritual. Science is a jealous mistress. Medical science is most jealous of all. It demands freedom of thought, concentration of interest and cooperation of all the related sciences. Cradled in Greece, the youth of medicine was no doubt spent in Rome, its adolescence in the Oriental nations, perhaps the first few years of its maturity in Germany and Austria. Today its finest offspring seem to be coming from America.

With a note of sadness one contemplates the destruction of all that was great in the medicine of Germany and Austria, the devastation of the medicine of France, the starvation of the medicine of Italy, the destitution even of the medicine of England. Yet that very situation gives to scientific medicine in the United States and in all the American nations an opportunity for progress beyond anything that has ever been available before. Let us not lose that opportunity.

The epochs of medicine and its advancement have been related to certain definite fields of investigation. One may point to periods known as the period of anatomy with Vesalius and the Italian school as its leaders, the period of physiology with Haller and Morgagni as its protagonists, the period of general medicine with Sydenham and Boerhaave, then the epoch of pathology with Virchow, the period of bacteriology with Pasteur and Robert Koch, next chemotherapy with Paul Ehrlich, and closely thereafter the vitamins, the hormones and the new chemotherapy. In this last stage of advancement many of the most notable contributions have been those of the Americans.

For many decades students of the American countries sought their medical education and their inspiration in the great medical schools, hospitals and clinics of Europe rather than in those of their own countries. Since the early part of the present century, however, medical education in the United States has advanced so tremendously that the schools now compare favorably with the best in the world. Moreover, the conditions associated with the war have depreciated greatly the quality of medical education in the Axis nations and have placed on the medical schools of the United Nations other than those of the Americans burdens which represent the most that they can possibly carry.

Many of the schools of medicine in the South American nations have also been improved tremendously in recent years, and special types of work which they are capable of offering cannot be found anywhere else in the world.

Opening address in the Session on Health Problems of the Americas before the Institute of Inter American Affairs, Columbia University, on the occasion of the four hundred and fiftieth anniversary of the discovery of the Americas. New York, Oct. 12, 1942.

An interchange of medical students has therefore already been started and will no doubt be greatly extended in the years to come. For instance, late in 1941, thirty-seven interns representing fifteen nations of South, Central and Caribbean America arrived in the United States to spend a year in the hospitals and medical schools of this country. The sponsors for this education included the Office of the Coordinator of Inter-American Affairs, the Pan American Sanitary Bureau and many of the leading American universities. The John Simon Guggenheim Memorial Foundation announced in 1941 twenty scholarships to Latin American scholars and artists for one year of study in the United States. Nine of these were in medical and related fields. They offered opportunity to young men of South American institutions especially well qualified to study problems in the field of neurology, endocrinology and physiology in leading institutions of North America.

The Commonwealth Fund of New York during 1942 offered through the Pan American Sanitary Bureau fifteen fellowships for one year's study of public health subjects or postgraduate medical courses to properly qualified students from South America. Each of these fellowships provides living allowances while the holder is in the United States, his travel costs and the costs of tuition.

The W. K. Kellogg Foundation, cooperating with the Division of Cultural Relationships of the Department of State and with the Pan American Congress of Ophthalmology, has arranged to bring twenty-five physicians of Latin American countries to the leading ophthalmologic institutions in the United States for one year of special training in that field.

Through the Coordinator of Inter-American Affairs and the United States Public Health Service twenty-two fellowships in public health and medicine for study in the United States were granted to medical graduates of 1940 and 1941 in the Latin American countries.

Early in 1942 a group of forty-two Latin American students were enabled to visit Columbia University for a period of six weeks under the auspices of the Institute of International Education. Included in this group were thirteen recent graduates of medical schools. A number of graduates of institutions in Chile also came for postgraduate courses under the auspices of the Chilean government.

At the same time many physicians from the United States have gone to South American nations in search of special information not available elsewhere. As a part of a health program recommended at the Conference of American Foreign Ministers, held early in 1942 in Rio de Janeiro, three physicians were assigned to carry on studies in Nicaragua, in Central America, in Brazil and in Bolivia.

The eleventh Pan American Sanitary Conference has just recently been completed in Rio de Janeiro, where attention was given particularly to problems of pneumoconiosis, brucellosis, typhus, parasitic conditions, diarrheas and the degenerative diseases.

These are but the first steps in the interchange of information and education necessary to bring about

cultural unity in the medical sciences on the American continent. The cutting off of our supplies of basic materials from the Far East and the demonstration that our South American neighbors may, with suitable encouragement, be able to develop adequate amounts of all these necessary substances, including rubber, quinine and many other materials, indicates that from every possible point of view the interests of the American nations must be unified. The leadership in this field, initiated by the Rockefeller Foundation, stimulated by the Pan American Sanitary Bureau and the Pan American Union and now intensified by the Division of Cultural Relations of the United States Department of State and the Office of the Coordinator of Inter-American Affairs, may be considered the necessary catalytic agent to arouse activity in all the nations intimately concerned.

PUBLICATIONS

From 1919 through 1928 the American Medical Association, aided by the Rockefeller Foundation, published in Spanish an edition of its official publication, *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*. This publication was discontinued in 1928 because it seemed to have served its purpose of introducing North American medicine into the Latin American countries and also because a considerable number of subscribers indicated at that time their desire to subscribe and to read regularly the English edition of *THE JOURNAL*. At present there are subscribers to *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* in every one of the South American countries and more than one hundred each in Argentina, Brazil, Cuba and Mexico.

Moreover, the Health Magazine published by the American Medical Association—*Higiene*—is widely circulated in the South American countries, particularly in Brazil, Colombia, Cuba, Mexico and Venezuela.

Especially significant also is the large subscription in Argentina to periodicals on diseases of children, neurology, dermatology, surgery and otolaryngology.

One of the difficulties in maintaining the Spanish edition of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* was the securing of the services of competent translators. In the years that have intervened since 1928, however, more and more attention has been given to the Spanish language in North America and to the English language in South America, so that the opportunity for a wider dissemination of information in the field of medical science is greater than ever previously.

CONVENTIONS

The extension of reciprocity in the dissemination of scientific medical information is encouraged furthermore by assemblages of scientific workers from all the Americas, which are becoming ever more frequent. Especially important in this connection was the attendance of guests from other American nations at the annual session of the American Medical Association held in June 1942. The presence of more than sixty physicians from Canada, thirteen representatives from Brazil, eleven from Cuba, ten from Colombia, nine from Argentina, seven from Mexico, seven from Chile,

five from Venezuela and others from Costa Rica, Peru, San Salvador, Uruguay, Bolivia and Paraguay indicated how greatly such a scientific session appeals to physicians everywhere. Many leaders from the South American nations participated in the program. There were receptions and entertainments especially planned for the guests, and many representatives of the Latin American nations urged that all future sessions of the American Medical Association feature the attendance of guests from other American countries.

Aided by the sponsorship of the Coordinator of Inter-American Affairs, twenty-one health officials from the South American nations attended the annual meeting of the American Public Health Association in 1941 and afterward traveled over the United States to study at first hand the public health methods of many of our large cities and states.

Several new publications are now being attempted with the view of cementing still further the mutual interest of the physicians of all the American countries. Many of the leading scientific periodicals of the United States now publish abstracts in Spanish, and some in both Spanish and Portuguese. Several publications designed particularly for reading in South American countries dealing with radiology and with surgery have recently begun publication and circulation. A digest publication known as *América Clínica* is now sent to some thousands of South American physicians in a venture in which the New York Academy of Medicine is largely participating. Moreover, negotiations are under way between the Office of the Coordinator of Inter-American Affairs and the officials of the American Medical Association to undertake the publication both in Spanish and in Portuguese of magazines intended particularly for extension of scientific medicine to all South American medical readers.

We in North America have for many years been greatly concerned in watching the progress of medical science, particularly research, in the South American centers. The work of the Chagas Institute in Brazil, of the Finlay Institute in Cuba, of the Biologic Institute at Butantan, of such leaders as Houssay and Rufto in Argentina, and of Lipschutz in Chile has long been known to investigators in the field of medical science in the United States.

Regularly all the important medical periodicals of South America have been indexed and catalogued and studied in the Army Medical Library in Washington, D. C., and in the library of the American Medical Association in Chicago. Here also the *Quarterly Cumulative Index Medicus* has listed the contents and cross indexed carefully the subjects concerned in all leading South American medical publications so that their contents would be made known to investigators in similar fields throughout the world. The constant and prompt interchange of medical information is fundamental to the dissemination and rapid advancement of medical science.

The publications of the Pan American Union and of the Pan American Sanitary Bureau indicate that certain problems of the South American nations which may be as much economic as scientific demand the aid of their North American neighbors for ultimate solution. In many of the centers of the United States improvement in nutrition has been steady and of vast importance in national progress. For years we have urged that every growing child should have at least a

quart of milk per day and every adult at least a pint. The consumption of milk in all the Latin American countries is admittedly too low, reaching in some places as little as one tenth of a quart per person daily and averaging perhaps one-half pint in places like Mexico City, Santiago, Chile, and other South American capitals.

The United States is perhaps overenthusiastic about vitamins and insufficiently enthusiastic about education regarding suitable diet. However, it is reported that 90 per cent of the Bolivians suffer from avitaminosis and that from 60 to 90 per cent of school and preschool children in Colombia, Costa Rica and Bolivia are subjects of malnutrition.

These are problems in which no nation has achieved perfection and in which all may be mutually helpful in finding solutions.

Good health is fundamental to human progress. The downfall of many a nation which had leadership in the world before may be definitely related to malaria, plague, cholera or smallpox. Fortunately the United States has been able to stamp out most of the great plagues which beset the rest of the world and through philanthropic and other agencies has given its help whenever possible to aid other nations in meeting these hazards. The incidence of infectious disease among the neighbors is a constant threat to the health of all. We have largely controlled malaria in the United States. We have stamped out yellow fever. Many of our largest cities are now able to report that they are free from deaths due to typhoid and diphtheria.

But now the world is aflame and we must never forget that infectious disease is one of the four horsemen that ride when wars are in progress. Today cholera is endemic in India and in Central China and it is reported that it has spread to Greece, the Balkans and Russia. Epidemic typhus fever threatens all of the Near East and has been reported in armies and prison camps elsewhere. Relapsing fever appears whenever typhus becomes a significant cause of death. Plague is prevalent in Java, India and China and has been detected among rodents in the Far West of the United States. The mosquito that carries yellow fever has been found in airplanes sailing into the United States from other nations. Constant vigilance is necessary in times like these for the protection of human health and life from such infections. Constant interchange of information from the health officials of all the Americas is necessary for the salvation of all the American people.

The Institute of American Affairs which has been going on here in Columbia University, jointly sponsored by the University and by the Inter-American University of the Air of the National Broadcasting Company, marks the four hundred and fiftieth anniversary of the discovery of the Americas. It is perhaps also a cause for congratulation that the opening sessions on this day, which commemorates the life of Christopher Columbus, should be devoted to an interest wholly humanitarian, wholly philanthropic, wholly scientific. Many of the discussions have been concerned with cultural, political and commercial subjects, but this session on the morning of October 12 is concerned with the protection of human health, the prevention of disease, the advancement of medical science and the saving of human life.

SPEEDING HEALTH PROGRESS
IN THE AMERICAS

WILBUR A. SAWYER, M.D.

Director of the International Health Division Rockefeller Foundation
NEW YORK

All the American countries are moving forward from the primitive condition in which medicine was exclusively occupied with the cure of fully developed disease toward that happy state in which well organized and adequately trained specialists will devote their entire time to the government service in community health protection. As the goal is approached the medical practitioners will undoubtedly place more emphasis on disease prevention in the families under their care, which will favorably affect community health, but my remarks will apply primarily to the public health field.

For over a quarter of a century the International Health Division of the Rockefeller Foundation has been cooperating with government health officials who wish to speed up progress by investigating troublesome problems, by trying out new methods or by study and observation in other countries. Service with this organization has given me the basis for my comments.

The rate of progress in health has varied among countries. Some have crawled along, others have walked briskly, while a few have taken leaps ahead. The public health movement has nevertheless evolved increasingly according to a common pattern, as the American countries have influenced one another through example and conference and have received assistance from the Pan American Sanitary Bureau, the Rockefeller Foundation and other agencies. The rate of gain has been increasing and the successes are becoming more numerous. Must this progress now be interrupted as the world war draws personnel, funds and materials from the protective purposes of public health to the destructive forces of war? Do the Americas have to declare an armistice in the war against disease? Most decidedly not. But why?

In the first place, the warring nations themselves will realize the importance of health protection for their civilian populations and industrial workers as well as for their fighters and will undoubtedly give a preferred position to their health organizations. But there are additional unique factors which brighten the picture for the Americas. Take the International Health Division's activities for an example. There never was a time when it could respond to all the offered opportunities for cooperation in promoting health activity. With its work in continental Europe and most of Asia inhibited by the war, personnel and funds have been released for application in those parts of South America in which its activities had been previously absent or slight. At the same time a much greater financial support to cooperative health work is coming to the Americas from the Institute of Inter-American Affairs, and the Pan American Sanitary Bureau is very active. The danger of confusion and overlapping of the programs of the various agencies was evident from the first, but it has been avoided to a degree beyond expectations by the laying of plans in frequent conferences between representatives of all the agencies involved, including the government health authorities, the Institute of Inter-American Affairs, the Pan American Sanitary Bureau and the International Health Division.

of the Rockefeller Foundation. The desire is to make the most of an exceptional opportunity and, if war-time shortages make one kind of program impracticable, to put emphasis on development of other public health functions and the training of the needed personnel.

There are certain policies for cooperative health work which have been tried by long experience and found to be good. All plans for cooperation with a government by an outside agency should at the start provide for the termination of the assistance under conditions which would facilitate continuation by government alone. This necessitates finding and training local leaders at the very beginning, by postgraduate studies in foreign countries if necessary. The size of the project, if it is the development of a permanent health service, must be such that the country can reasonably be expected to maintain it at the level reached at the end of the cooperative period of exploration, organization and demonstration. Foreign personnel representing the cooperating agency should live at the seat of activity, learn the local language, become sympathetically acquainted with the people and try to understand the local factors which make necessary certain differences between countries in methods of organization and procedure. At the same time representatives should stand firmly for such fundamental principles as full time service to a single salaried position and adequate training for the technical men directing a service or carrying on its essential work. Any permanent activity should, if possible, be truly cooperative from the beginning to such an extent that the country benefited contributes toward the funds and its nationals play an important part.

A few examples from South America will show striking successes and will help foretell the future of public health in that region. The partial failures we can pass over as temporary incidents.

Venezuela stands out as a country which has been following the slow but sound method of training an adequate number of expert health officials in foreign schools from year to year and depending on them after their return to establish the health structure. A school for nurses is being developed so that the necessary number of public health nurses will ultimately be available.

In many other countries will be found health experts trained in foreign countries under fellowships provided by their governments, the International Health Division or other agencies and pledged to devote themselves to governmental health work. They are perhaps the greatest single asset to the public health movement, and without them increased expenditures would be largely wasted.

The most spectacular successes have been in the conquest of dramatic plagues, particularly yellow fever. All are familiar with the early announcement by Carlos Finlay of Cuba that yellow fever was transmitted by a mosquito, now known as *Aedes aegypti*, and the later convincing proof of this in Cuba by the United States Army Commission under Walter Reed. The control of yellow fever in many cities and countries followed, with the first great demonstrations by Gorgas in Havana and Panama and Oswaldo Cruz in Rio de Janeiro. It is less widely known that Brazil, with cooperation from the International Health Division, has in recent years so improved and applied *aegypti* control that its coastal cities are noninfective with yellow fever. In fact the methods of systematically detecting and destroying this mosquito have become so efficient that

the species can be locally exterminated at will if the will is supplemented with funds and organization, and it is now reported that in six Brazilian states and the Federal District aegypti can no longer be found. The control organization, now wholly under Brazilian medical directors, is pressing to exterminate this dangerous mosquito from an ever increasing area of their country. This success has attracted wide attention, and scientists have gone to Brazil from Europe, Africa and several American countries to see for themselves and learn.

Another discovery of worldwide significance was made in Brazil through the cooperative yellow fever work. As the coastal cities and the surrounding areas were cleared of aegypti mosquitoes there continued to be cases of yellow fever in the interior. This led to the unexpected discovery in 1932 that yellow fever could be transmitted by mosquitoes of the tropical forest other than aegypti, and even in the absence of human cases of the disease. This meant that jungle animals must be capable of multiplying the virus and infecting the mosquitoes. The basic discovery was made in Brazil, but the subsequent fruitful study of the epidemiology of the disease and its control through a method of vaccination devised in the United States of America was carried on both in Brazil and in Colombia.

The success in the local extermination of aegypti raised the hope that other dangerous mosquitoes with domestic habits could be eliminated. When the highly efficient malaria transmitter *Anopheles gambiae* was accidentally introduced from Africa into northeastern Brazil, it spread the local malaria until devastating epidemics with high mortality occurred. In eight years this mosquito had advanced over an area of about 12,000 square miles. A special service with staff of over two thousand men was organized. Many with experience in the yellow fever service were included. The infected area was mapped and districted, larvae were destroyed by the application of paris green, adult mosquitoes were killed by sprays in the houses and vehicles were disinfected at the boundaries of the area. Early in 1940 the control measures were stopped, and since then a diligent inspection service has been unable to find a single *Anopheles gambiae* mosquito. It will take great vigilance to prevent the reentry of this unwelcome invader into the Western Hemisphere, for dead *gambiae* have been collected after the spraying of planes coming to Brazil from Africa, and any slip in the precautions might reinfest South America. The complete extermination of this species has no parallel in public health experience, although there have been somewhat similar successes in the field of agriculture.

These few examples of health work in South America cannot but convince us that, if such appalling health menaces can be promptly studied and conquered, the other health problems of the Americas will be solved in due course. The time may soon come when a greater appreciation of what is being done in the health field in South and Central America and the West Indies will result in an increase in the number of men going from the United States of America to the countries of the south to study disease prevention, particularly with the present awakened interest in tropical diseases.

What of the future? As success rewards the efforts to meet our present disease problems, standards will rise and new problems will appear or old neglected ones will become more important. As populations increase and travel becomes more rapid, greater precautions and more effective methods will be necessary to curb infectious diseases and to keep from spreading

dangerous insects. All these demands can be met only through scientific research and effective organization. Successful results will come faster if the pace now stimulated by war is not allowed to slow down with the advent of peace.

The first health duty of every American country is to see that the minima of standard health precautions are met by their communities. These minima should include safe piped water available throughout the day and night in every home or place of work, adequate sewerage and competent health supervision. Such supervision will require medical health officials with postgraduate training in public health, bacteriologists, public health nurses, sanitary engineers and vital statisticians in the larger centers, and at least trained full time health officers with public health nurses in all cities and the larger towns. These smaller units will need the occasional help of central government epidemiologists and laboratory experts if they are to be ready at all times to identify and control the unusual diseases. The constant diagnostic service of a central laboratory is indispensable.

With the increased establishment of sound health organization with adequate support throughout the Americas, we can face with assurance the temporary problems raised by the war and look confidently toward levels of health and well-being as yet undreamed of.

THE EXCHANGE FELLOWSHIP

A SOUND BASIS FOR ENDURING INTER-AMERICAN CULTURAL RELATIONS

DR. JOAO JACQUIS DORNELLES

RIO DE JANEIRO, BRAZIL

It is difficult to discuss plans for the creation of mutual understanding between the Americas unless we consider first the circumstances surrounding the indifference to one another from which these two continents have suffered until very recently. The Western Hemisphere is, for the purposes of a broad discussion of our present civilization, young and vital, not yet fully aware of the enormous implications of strength and greatness which lie in our natural resources and our cultural heritage.

Both continents owe, in common, their debt of discovery to the spirit of the Renaissance which drove European adventurers to the West. From the very beginning there were however, habits of mind and historical association bound to produce very different methods of adaptation to the environment of the new worlds of North and South America.

Here in the North there grew out of revolution, expansion and industrialization a new culture, strong as the desire for liberty itself. It may perhaps be said that this distinctive North American character began to assert itself clearly about one hundred years or better, eighty years ago, directly after the Civil War. The United States we know today has been proved a nation indivisible. It began to draw away from European influence.

But south of the Rio Grande the pattern was a different one. The countries of Latin America had maintained close ties with Europe and even until recently the development of a civilization truly Western, strengthened by the bonds of cultural exchange with

the North, was very slow. There was, and quite naturally, a preoccupation with national problems in the United States which precluded the realization that one half of the hemisphere was almost unknown.

We are therefore dealing with a relatively new idea.

We are bent on finding a sound basis for enduring Inter-American cultural relations.

I have been asked, as a member of the medical profession and a Latin American, to discuss this subject as it is based on the exchange of scientific knowledge between the western continents. I am one of 3,400 visitors from South America this year, one of 160 doctors. Had I come fifty years ago I would almost surely have been the only one here. Even twenty-five years ago there was very little interchange of professional activity between the North and the South.

In 1914 Benedict Montenegro, now dean of the Faculty of São Paulo, came from my country, Brazil, to study at the University of Pennsylvania. In 1918 Dr. Borges Vieira and Dr. Paulo Souza were in the first class at Johns Hopkins University School of Hygiene with fellowships granted by the Rockefeller Foundation. In 1920 Dr. Carlos Chagas attended a public health conference in Boston, on which occasion the degree of Master of Arts Honoris Causa was conferred on him by Harvard University. In every country of South America there were similar cases in which doctors pioneered in the exchange of medical information.

In 1937 the Buenos Aires Convention for the Promotion of Inter-American Cultural Relations gave great impetus to the movement which had been so well begun by private individuals and the Rockefeller and Guggenheim foundations. According to the provisions of this convention, fellowships were granted to qualified representatives of every Latin American country through the Department of State. And, for the first time, actual internships were arranged by the Pan American Sanitary Bureau for visiting doctors in the finest hospitals of the United States. It is impossible to overemphasize the importance of this last provision involving internships, for the language handicap, in combination with new methods of teaching, had made it exceedingly hard for exchange fellows who were only observers to take advantage of opportunities to learn that which lay always before them but almost out of reach.

When this activity had begun to assume national proportions, the American Medical Association, which has long guarded the high standards of medical teaching and practice, undertook to encourage hospitals to accept students from Latin America. It may be a matter of conjecture, certainly a source of great hope, that one day this association will list among the requirements for accredited hospitals a provision for exchange fellowships and internships.

Most doctors who study in foreign lands mean to do postgraduate work. Many of them have already begun private practice. As a rule they cannot afford to remain away from home for more than one year. As clinical observers they encounter great difficulties when they cannot ask questions in their native languages. It is also hard for them to follow lectures, which are, however, always exceedingly helpful as they are understood.

Here in the United States postgraduate study involves three long years of intense work. To come to this country for a single year is almost a waste of

time, for the course is so arranged that the work of the first year is purely preliminary, meaningless, until it fits into the program of the second and third years. It is true that any man who is able to go through the whole course will return to his native land with a solid background in his field. But if the American Medical Association could work out a plan through which visiting doctors could be exposed, in one year, to a comprehensive view of their special departments of medicine, they could then go home to continue their work along new lines. The beneficial effects of such an arrangement are numerous. First, those doctors who are well qualified but unable to afford three years away from private practice would then be able to take advantage of exchange fellowship opportunities. Then also for every one man who now studies abroad there would then be three to gain this valuable experience. And the results which would accrue from the exposure of large numbers of doctors to new ideas would, of course, advance in an arithmetical progression and so intensify interest among their fellow men in the hemispheric view of their profession.

What is true of medicine is true of every other branch of knowledge, fellowships are a vital link in the dissemination of our culture throughout the Americas.

In medicine alone there are here in the United States representatives of every country in Latin America. They are at work in some of the greatest hospitals and medical schools in the world—at Harvard, at Yale, Chicago, Ann Arbor, California, St. Louis, at the Mayo Clinic, at the College of Physicians and Surgeons, at Memorial Hospital and New York Hospital, to cite only a few. Of Johns Hopkins special mention should be made, for in years past when there was very little interchange among our nations it stood out like a beacon among the medical schools of the New World. By way of illustrating the rapid growth of professional good neighbor policy, one can point to the Memorial Hospital here in New York, where a great fight against cancer is being waged. When Dr. James Ewing and Dr. George T. Pack visited South America recently they found among doctors and medical students an increasing interest in the battle against cancer, and following their return to Memorial Hospital the number of interns, surgical assistants and special fellows from Latin American countries has at least doubled.

The preservation of peace and harmony is the objective toward which our foreign policies are directed. We are now employing every means available to buttress the social, political and economic structure of our hemisphere with sound cultural relations which will outlive the circumstances of an era of world conflict. Culture is a social phenomenon which draws its strength from a hundred sources, its endurance from the nature of these sources. The path along which we are now moving presents our greatest hope for a bright future for the western world.

Today we commemorate the four hundred and fiftieth anniversary of the discovery of the Americas by Christopher Columbus. It is most appropriate that we should concern ourselves with the coordination of the numerous forces which are now devoted to the cause of uniting the nations of this hemisphere.

I am honored to have had this opportunity to tell you of the cooperation which now exists among the members of my profession and to have been able to give

some small measure of credit due those organizations which have done so much for the cause of a united America

In my work here I have merely made a beginning, for in future years I shall be able to disseminate among my people that long view which I have here acquired. This will be a pleasure and an honor of which no man could be more proud.

INDUSTRIAL AND HEALTH DEVELOPMENT IN THE TROPICS

ALBERT R. DREISBACH, M.D.

Assistant to Director, Health and Sanitation Division
Office of Inter American Affairs

WASHINGTON, D. C.

Health and sanitation planning in wartime takes on increased importance for the public welfare. War is destruction, whether of human life or of property. Yet at the same time it sets in motion countermeasures for protection of human life. It is one of these wartime efforts to preserve human life that I am going to discuss here. I appreciate this opportunity to tell about a phase of inter-American activity that, while developed in wartime, promises to be of lasting benefit to the Americas cooperating in this humanitarian work.

Other speakers on this program are discussing the broader phases of inter-American achievements in health and sanitation. The program being carried out by the Health and Sanitation Division of the Office of Inter-American Affairs, in cooperation with the other Americas, has the help of the work done by pioneers in tropical medicine. This program springs from the necessities of wartime development, although it aims to provide long range benefits for peace as well as to meet wartime needs. The Pan American Sanitary Bureau, the health and sanitation authorities of the other Americas, medical schools and private organizations have a notable record of accomplishment in raising health standards in the Americas.

We are grateful for the cooperation we have received from the established institutions in this field. Their experience and help have been invaluable in getting this large scale organization under way. The new program is designed to supplement, rather than supplant, the activities of the established agencies. The fruitful work of these organizations should continue to grow.

The program started by the Americas this year was recommended in a resolution passed at the Rio de Janeiro Conference of American Foreign Ministers last January. That conference, you may recall, met at a crucial time. It was summoned after the Japanese attack on Pearl Harbor. The Rio conference recommended a many-sided program of cooperation for development of hemisphere economic resources, for control of anti-American activities and for defense of the Americas.

The conference proposed that the American republics take individually, or through agreements between two or more of them, appropriate steps to deal with problems of public health and sanitation. The conference suggested, furthermore, that such cooperative action be undertaken in accordance with the ability of the separate countries to provide raw materials, services and funds.

It was necessary to move fast to get this program into action. The urgency of the Rio development pro-

gram soon became evident after the fall of Singapore. In the Far Eastern trade area guarded by Singapore, the United Nations lost their principal sources of rubber, quinine, manila hemp and substantial supplies of metals, vegetable oils and other vital materials. These supply losses can be replaced in part or wholly from the Western Hemisphere. But a big job of organization is involved. The Rio conference provided the framework for cooperation in the organization of hemisphere resources to produce supplies needed by United Nations war industry and for replacement of imports formerly obtained outside the hemisphere.

It was necessary to begin the health and sanitation work immediately. This program had to precede, in part, actual development work. Experience has taught the need of preparation for protection of workers in tropical areas. Besides economic developments there also was need of health and sanitation measures for defense projects. Altogether these made a formidable task of health and sanitation planning. Considering the expense, the necessity of close cooperation among governments of the Americas and the urgency of it, this program inevitably became a government undertaking.

To carry out the Washington end of the program, a health and sanitation division was set up in the Office of Inter-American Affairs under the direction of Dr. George C. Dunham. Dr. Dunham had many years of experience in tropical health and sanitation work in the Philippines and in the Americas to the south. The coordinator of Inter-American Affairs, Nelson A. Rockefeller, long had recognized the importance of health and sanitation in inter-American relations and readily lent his support for the execution of the Rio conference recommendation.

Today the program is well under way. Parties of tropical medical specialists, sanitary engineers and other technicians are in the field in eleven of the republics to the south, collaborating with health authorities and medical specialists of those countries in many projects. Far into the interior of the vast Amazon Basin, these men prepare the way for thousands of additional tappers who will be needed to collect wild rubber for the United States market. The United States has signed agreements with fifteen of the rubber producing Americas to purchase their exportable rubber surplus. Health and sanitation projects are tied in closely with the rubber program. In Haiti it ties in with plans for growing sisal for the United States market. Likewise it connects with other developments immediately designed to aid the war effort but likely to be productive also of lasting benefits.

I have not time to discuss in detail the reasons why health and sanitation planning must be part of industrial development in the tropics. Others on this program are discussing the more general phases of hemisphere health problems. Suffice it to point out here that malaria, one of the greatest scourges of mankind, is particularly prevalent in the rubber producing areas. Malaria can be more deadly than bombs and bullets when masses of men are involved in such tasks as tapping rubber trees in tropical forests. In the first wild rubber boom in the Amazon Basin many years ago the rubber collector ranged into mosquito infested tropical forests at his own risk. What that risk meant in disease and death may be seen in accounts of the human toll taken in the feverish rubber boom before the first world war. I say feverish in a double sense, for it was permeated with malaria.

Let me quote what the Brazilian newspaper *A Noite* says about malaria in an article applauding the Brazilian health and sanitation project. This article points out that malaria, starting at Bahia, spreads all the way into the state of Acre in the extreme western part of Brazil and into Bolivia and Peru. I quote from the article:

Raging unchecked, this malady has claimed thousands of lives each year and is the chief obstacle to the development of the area. It is mainly in the vast, mysterious valley of the Amazon, from the islands of the long estuary near Belem, past Amazzonas, Purus, Iaco, Madeira and Acre, that malarial fever rages at will, without shackles or organized resistance, except by the dangerous individual treatment, at best unsystematic and sporadic, of quinine.

One of the veterans of tropical medicine at work on the Amazon project is Dr. K. C. Waddell. Before he joined the inter-American project, Dr. Waddell for six years was with the Ford rubber plantations in the Amazon. This was the biggest rubber plantation project started in the hemisphere prior to the war. The experience of Dr. Waddell is now invaluable for large scale organization of such work in the Amazon territory.

From a branch field office in Manaus, deep in the interior of Brazil, Dr. Waddell and his men are working with Brazilian authorities in a campaign against malaria. It isn't a spectacular campaign compared with the drama of the front line fighting fronts in the world struggle. But it is work which is essential to development of hemisphere resources. It holds possibilities of huge, though intangible rewards in human happiness.

Malaria control is varied. It may be directed toward elimination of mosquito breeding places, mosquito proofing of dwellings, construction of screened houses, distribution of quinine or substitutes and so on. Projects in this program are adapted to local conditions. The Americas to the south are highly diversified in climate, geography, peoples. They require individual attention. Besides Brazil, health and sanitation missions have been assigned on request from these countries to Peru, Bolivia, Ecuador, Costa Rica, El Salvador, Guatemala, Haiti, Honduras, Nicaragua and Paraguay.

To illustrate the variety of work, I shall enumerate some projects. In Peru plans have been made for completion of a hospital at Tingo Maria, an agricultural research and development center on the eastern slopes of the Andes. Hospitals and dispensaries are proposed for other Peruvian towns suitably located to serve strategic producing areas.

In northeastern Bolivia, a rubber area, malaria is the chief health problem. So the sanitation of Guayara Merin was selected for the first project by Bolivian and United States medical specialists under this program. The town selected is the head of navigation on the Madeira River, one of the main tributaries of the Amazon. It is the port of entry between Bolivia and Brazil.

Work is further along in Ecuador. The work in Ecuador includes improvement of sewerage and hospital facilities in Quito, the capital, also malaria control projects near Guayaquil, the chief port of Ecuador. In Haiti, besides malaria control, sanitation work includes the construction of a rural market just outside the city of Port-au-Prince. Offhand the building of a rural market may sound remote from health planning. But the marketplace fits in well with the program. The reason is that the marketplace in Haiti is a public gathering place and one of the best points from which to disseminate health information. In Nicaragua the plans include construction of headquarters in Managua for the Nica-

raguan health administration. In Paraguay a site has been obtained for a health center in Asuncion, the capital.

These examples illustrate the varied nature of the projects. They also may serve to indicate the permanent benefits that should flow from this program. These new hospitals, sewerage and market facilities and malaria control should prove valuable in peace as in war. It is wartime necessity that expedites the program. But, once under way, health and sanitation work gathers momentum, carries on long after the start.

This is proved in the achievements of such established institutions as the Pan American Sanitary Bureau, the health activities of the other Americas and of private organizations. From the projects described here, it is possible to envisage substantial benefits for the post-war as well as the war period. Many additional people in the other Americas are drawn into health work as a result of these projects. Many additional nurses and technicians must be trained. This additional trained personnel likewise may be accepted as a lasting contribution to improvement of health and sanitation conditions in the Americas. Thus amid the destruction of war there emerge new constructive forces. We may justifiably hope that these constructive forces in health and sanitation will serve as both immediate and long range influences for continued growth of inter-American cooperation and understanding.

ATYPICAL LARYNGEAL AND VOCAL CHANGES IN ADOLESCENCE

JAMES SONNETT GREENE, M.D.

NEW YORK

Adolescence has been aptly termed the "fateful passage." It is a period of tremendous upheaval when, among other things, nature reorganizes the entire body to assume the function of reproduction. It is small wonder, in view of the far reaching somatic changes which occur within a comparatively short period, that many disorders are precipitated during these adolescent years. In fact, the biologic changes are so radical and offer such a plausible explanation for almost any condition which develops at this time that too often

Fig. 1—Range of voice of patient whose likeness is shown in figure 2 before and after treatment for paraphonia.

one attributes to them disorders which are not primarily of organic origin at all but are instead largely psychogenic.

Concomitant with and indeed arising out of the somatic changes of adolescence, there is a great emotional upheaval. The child's biologic maturity makes new exactions on him. He finds himself beset by strong unconscious impulses which he does not understand and with which he does not know how to cope. The

environment as well imposes new, different and often difficult demands. Frequently these demands are conflicting. For instance, parents, confused by the boy's or girl's sudden transition from childhood, are at a loss as to how to balance freedom and discipline and, too often, continue to treat the adolescent as a child attempting to repress all expression of his increasing maturity and all his natural impulses toward independence. At the same time, the outside world expects the individual to act in accordance with his greater physical maturity. This disharmony between parental exactions and environmental demands outside the home inevitably gives rise to conflicts.

Physicians and teachers are frequently at a loss as to how to advise parents because there is no master plan for the adolescent. While it is true that all adolescents pass through an orderly sequence of growth, development and maturation, each one—depending on his nature (his inherent constitutional endowment) and the adequacy of his nurture—will pass through this sequence at his own rate. Thus there is a great variation in the rates at which the same changes take place in different individuals. Furthermore, even within the individual himself there are variations in the rates with which different functions become fully organized. Thus the whole organism is in a general state of instability as regards both its internal and its external interrelationships.

If the instability is especially pronounced, and if environmental pressures are strong, the adolescent will feel particularly inadequate to the demands which his

This disorder is usually demonstrated by the timid boy who fears the grown-up masculine role. Such a boy may protest against assuming that role by unconsciously clinging to his high, piping childish treble. Through constant use of his high voice, he causes a faulty coordi-

Fig 2—Appearance of P. W. aged 15. This patient with a falsetto voice shows no morphologic deviation from the average boy of his age.

biologic maturity imposes on him, and he may unconsciously resort to some neurotic solution. This frequently takes the form of a vocal or speech disorder. For example, the adolescent boy's voice may fail to change, the high pitch which was normal in childhood becomes abnormal in adolescence, and the condition is diagnosed as paraphonia or falsetto voice.

Fig 3—Appearance of J. C. aged 16 whose falsetto voice was associated with an endocrine involvement. The patient is of the eunuchoid type, presenting the typical Frohlich syndrome with its characteristic female distribution of fat around the hips and breasts, large abdomen and under developed genitalia.

Fig 4—Appearance of H. B. aged 20 whose falsetto voice was also associated with an endocrine involvement. While he presents an altogether different picture from the Frohlich type it is nevertheless apparent that morphologically he too is typical.

nation and misdirection of the laryngeal musculature, inhibiting the depressor muscles from assuming their normal dominance. Thus, the levator muscles (the suprhyoid group) retain dominance, and the larynx remains in its abnormally high position in the throat.

The condition, if uncorrected, continues throughout adult life, long after it has ceased to have any usefulness as a defense mechanism. Indeed in time it becomes a definite liability, and the resulting psychic traumas have far reaching and serious effects on the personality. For instance, recently I had a patient with a falsetto voice, a man aged 50 and the father of three children, who told me that he had "suffered the tortures of the damned" and had shunned all social contacts because of his voice. I have a record of his voice before and after treatment, but since I am discussing the adolescent, I present here the recording of a younger patient, a boy aged 15 (fig 1), before and after treatment.

This boy was referred to me by the school authorities, who noted that, while the voices of his schoolmates had all changed, his still remained high. This was beginning to have a detrimental effect on the boy's personality.

RECORDINGS

It will be noticed that there is nothing to distinguish this patient (fig 2) from the average boy of his age. Cases of this sort are not to be confused with those in which there is an endocrine involvement, in such cases the vocal disorder is but one aspect of the whole symptom complex. It is comparatively easy for the diagnostician to recognize the endocrine type merely by observation of the picture which the patient presents. He usually shows an apparent deviation from the so-called morphologic normal. For instance, he may present the typical Frohlich syndrome with its characteristic female distribution of fat around the hips and breasts, large abdomen and underdevelopment of the genitalia (fig 3). Such a patient is definitely recognizable as a eunuchoid type.

On the other hand, the patient with an endocrine involvement may be an elongated eunuchoid type (fig 4). While he presents an altogether different picture from the Frohlich type, it is nevertheless apparent that he also is atypical.

Another patient may present a still different syndrome—a picture of general underdevelopment. The most interesting study of this type that I have made was on identical twins referred to me by Dr. George B. Dorft of the Children's Medical Service of Bellevue Hospital. These boys suffered from cryptorchism and

there was nothing significant in their infantile history. On examination they were fairly well nourished but showed definite stunting. They both suffered from cryptorchism, and the external genitalia were infantile. They were kept under periodic observation until they

Fig. 6—Appearance of Pz twins at the age of 13 after one had been treated for eight months with chorionic gonadotropic substance. Although originally shorter and lighter in weight (the twin to the left in figure 5), the treated twin was now 2 inches taller and 8 pounds heavier than his brother. Normal pubertal changes had taken place and his voice had become low and resonant. The untreated twin remained underdeveloped and retained his high pitched, childish voice.

Fig. 5—Appearance of Pz twins at the age of 7½ years. They are identical twins with cryptorchism.

had been underdeveloped in every way. I first saw them at the age of 13 years. However, they came to the attention of Dr. Dorft at the age of 7½ years (fig 5) when their father brought them to the Children's Endocrine Clinic complaining that they were not growing sufficiently. Delivery had been normal and

were 12, during which time Richard was given desiccated thyroid with no apparent results. He showed no greater increase in height than Joseph, the control, who received no thyroid. At the age of 12 it was decided to treat one of the twins with chorionic gonadotropic substance. Since Richard was the shorter twin and weighed less than his brother, he was chosen for treatment, while Joseph was again selected as the control and given no medication. Richard was given from 200 to 500 rat units of chorionic gonadotropin three times a week until a total of 42,850 rat units had been given. At the end of eight months treatment was discontinued, and it was at this time that I saw the twins. Richard looked more mature than Joseph in every respect (fig 6). Although originally shorter and lighter in weight, he was now 2 inches (5 cm) taller and 8 pounds (3.6 Kg) heavier than his twin. He was making so much better progress in school that he was promoted a class while his untreated twin remained behind. In addition, the endocrine therapy had produced normal pubertal changes in Richard. And, what particularly interested me, Richard's voice had become low and resonant—it was a normal adult male voice—while Joseph's voice remained high pitched and childish.

DYSPHEMIA

Another disorder which is frequently seen in the adolescent is dysphemia, or stuttering. While in the majority of cases this disorder develops earlier in life, the general instability of the organism during the pubescent period, as well as the heavier environmental load, serves to increase its severity at this time. Moreover, the adolescent begins to realize the social implications of his stuttering, which gives a further impetus to the development of his anxiety neurosis.

It is inevitable that the child who stutters should be more than ordinarily affected by the stresses and strains of adolescence. His speech disorder is evidence that he already possesses a physiologically unstable organism, for stuttering speech is a somatic manifestation

of an emotional disorder—an emotional disorder which is, in turn, based on a constitutional predisposition to nervous disorganization. The pressures of adolescence increase this potential instability, accentuating the child's feeling of inadequacy and causing his stuttering to become more severe.

CASE 1—D W, aged 15, the son of a college professor, had stuttered since childhood. However, the disorder was not severe enough to disturb him greatly, and he managed to overcompensate for it by being unusually aggressive and leading his "gang" in various childhood exploits. During adolescence the stuttering speech became more pronounced, reflecting the greater instability of the organism. The patient's concern over it increased and he began to have a conscious feeling of inadequacy and anxiety. When he was referred to us, his stuttering was very pronounced.

Treatment was along our usual eclectic lines to increase the underlying efficiency of the organism, eukinetics, rhythmic and relaxation therapy were introduced, also the patient was given both group and individual psychotherapy, in addition a certain amount of speech reeducation was introduced to break down his old fear response in speech situations and, at the same time, build up his confidence in meeting such situations. All this was supplemented by social therapy, which is an integral part of our therapeutic program at the National Hospital for Speech Disorders. When the patient returned to school, there was a noticeable change in his personality and in his speech.

PSYCHOPHONASTHENIA

A third condition which may develop in adolescence is psychophonasthenia—a pinched, grating voice with pitch irregularities, a voice that "cracks" frequently, breaking suddenly into another key or choking off completely. There is usually no local pathologic condition, if such a condition is present, it is so slight as to be entirely disproportionate to the severity of the vocal involvement. The disorder is fundamentally one of psychic origin—a symptom of neurotic anxiety—and its onset can usually be traced to some crisis in the person's life or to suddenly increased environmental pressure.

CASE 2—S M, aged 16, the daughter of a high school principal, developed psychophonasthenia shortly after transferring from one school to another. When questioned about her school work she confessed that she was not a good student, had "flunked" several subjects during the course of her scholastic career, and was at the time of the interview being tutored in French and English. Since, in spite of her below average scholastic ability, the patient was a senior in high school at the comparatively early age of 16, it was evident that great pressure had been brought to bear to push her ahead. She had been pushed beyond her capacity, in a sense, the child was a sacrifice to the pride of her highly educated parents.

She admitted having always been afraid of her teachers and of being "very nervous" whenever she had to recite, but she had never experienced any actual difficulty in speaking until transference to the new school environment. This change placed an added burden of adjustment on the child which the organism was incapable of withstanding. It was, so to speak, "the straw that broke the camel's back."

Since psychophonasthenia is the culmination of a neurosis which has been developing over a period of years, it is a deep-seated disorder and difficult to treat once it has become firmly rooted. For that reason an effort was made to impress on the parents of S M the necessity of taking the girl out of school and of having her receive treatment while the vocal disorder was in its initial stages. The parents rejected this suggestion on the ground that her graduation from high school was at the moment of primary importance and that, in any event, since the disorder had developed suddenly, the patient would undoubtedly "grow out of it." In my experience with psychophonasthenia, I have never

known of a case in which there has been a spontaneous resolution, and I expect to see this patient again in a year or two, her neurotic traits much more deeply ingrained and presenting a much more difficult therapeutic problem.

HYSTERICAL APHONIA

Another vocal condition occasionally seen in adolescence, particularly in adolescent girls, is hysterical aphonia—sudden loss of voice due to psychic conflict. It is usually an unconscious means of escape from something in the environment which is distasteful or which threatens the person's security or happiness.

CASE 3—M C, a girl aged 15, was brought to the clinic because she had suddenly lost her voice several months before and had since been unable to speak above a whisper. Laryngeal findings were essentially negative, as is usual in these cases. However, a careful anamnesis revealed that the patient had a Latin teacher whom she disliked and who created strong tension feelings every time the patient recited. The fact that the patient was not a particularly good Latin scholar added to her dislike of the class. By losing her voice, she escaped from the necessity of reciting, and invited her teacher's criticism.

The patient's voice was readily restored, and a brief period of psychotherapy was introduced to give her an insight into the reason for the aphonia and to change her outlook on the causative environmental factor. There has been no recurrence of the condition.

CONCLUSION

The point I should like to emphasize is that the conditions underlying all these vocal and speech disorders do not suddenly develop at adolescence. It is true that the stresses and strains of this period may precipitate the acute symptom—the vocal or speech disorder—but the condition giving rise to it has been present and has been developing long before the adolescent years.

The pediatrician with this in mind can often detect these "disorders in the making." The nervous, disorganized child may become the adolescent stutterer. The inhibited, fearful, seclusive child may become the psychophonasthenic person of tomorrow. The timid, sensitive or effeminate boy may develop into the typical falsetto voice patient. The "flighty," overemotional child who uses temper tantrums to achieve her objectives or to evade unpleasant realities may, later in life, unconsciously resort to hysterical aphonia to accomplish the same end. The physician who sees these children early in life and recognizes their atypical behavior problems as indicative of maladjustment can, by judicious guidance, often prevent many acute and even disabling conditions from developing later on. Prophylaxis is, after all, the highest function of medicine.

61 Irving Place

ABSTRACT OF DISCUSSION

DR. GEORGE B. DORFF, Brooklyn. This paper of Dr. Greene's, who has been a pioneer in speech disorders, has opened up certain new angles. Primarily I am interested in the endocrine aspects of these boys, and I know the difficulties that adolescents and adults, particularly those who are eunuchoids or sexually underdeveloped, have when these voice changes do not. Just the other day at the meeting of the Association for the Study of Internal Secretions Dr. Pratt presented a case of a eunuchoid doctor about 30 years of age, who had a high pitched voice and was quite embarrassed. Under treatment with androgen there were produced definite changes in his makeup and particularly in his voice. In these eunuchoid types, particularly in the adult, the disturbance of voice and the appearance—lack of beard and the like—are the characteristics which worry the persons involved. It is not so much sexual because they are not aware of what sex means, but changes in the voice and facial appearance are the important things. Thus we have

here, from the endocrine point of view, a means of modifying the voice at least, if not also the genitals, in these types of cases in adolescents and some of the adults. In the last few years we have been able to stimulate certain processes in general, not only from a sexual standpoint but from a physical, a growth standpoint, and I am not referring to the use of commercial anterior pituitary growth hormone. We are doing it by way of the genital apparatus. By stimulating the gonads and developing the patient we can accelerate linear growth and produce puberal changes, as I did in one of the twins presented.

ORAL MANIFESTATIONS OF OCCUPATIONAL ORIGIN

ISAAC SCHOUR, DDS, PhD

AND

BERNARD G. SARNAT, MD

CHICAGO

Our purpose in this report is to present a summary and analysis of the available information on oral occupational disease. The increase in occupational hazards and exposures coincident with the speeding up of industrial activities in the present emergency presents a special challenge to the medical profession to maintain the health of the worker. It is the private physician who sees most of the industrial workers. He is therefore the first to recognize early symptoms and findings of occupational diseases, many of which are in the oral cavity.

Ramazzini¹ (1633-1714), "the father of industrial hygiene," was the first to advocate the inclusion of the patient's occupation in each medical history and to point out a number of oral symptoms. In 1690 he warned painters against wiping brushes on their lips, and yet only recently the lives of a number of workers were lost because, in disregard to this simple precaution, they used their lips to moisten and point the brushes in painting luminous watch dials.

There are a limited number of reports and reviews² on oral occupational diseases, the most complete of which is by Koelsch.³ Many of the available references are statements of descriptive rather than analytic nature. Direct investigations of carefully controlled cases are not common. There are several excellent textbooks⁴ on occupational disease which present occasional references to oral lesions.

From the Department of Histology, University of Illinois—College of Dentistry.

Read before the fourth annual Congress on Industrial Health, Chicago, Jan. 14, 1942.

Drs. M. H. Kronenberg, chief of the Division of Industrial Hygiene, Illinois Department of Public Health, and C. M. Peterson, secretary of the Council on Industrial Health, American Medical Association, encouraged the authors in this study.

In evaluating the data in the literature one must realize that in instances in which working conditions have been sufficiently improved the associated manifestations previously reported are now of only historical interest. However, the limited supply of stocks essential to the war effort has necessitated substitutions involving the use of discarded methods and materials. It is not unlikely that occupational diseases previously eliminated may now reappear. Furthermore, with each succeeding change in industry new oral manifestations may arise.

Relatively few oral manifestations are included in the compilation of occupational disease symptoms in the 1941 Standard Bodyparts Adjustment Guide⁵ prepared for insurance companies. It is quite possible that oral manifestations did occur but were not recognized by the examiners. It appears that neither the physician nor the dentist is sufficiently aware of the possible oral manifestations or actively interested in their recognition except after definite complaints by the patients.

This report attempts to analyze the various aspects of oral occupational disease on the basis of the following considerations:

1. The structure affected (table 1)
2. The pathologic process (table 2)
3. The etiologic agent (table 3)
4. The occupational incidence (table 4)

PHYSIOLOGY OF THE ORAL CAVITY

The oral cavity is a port of entry for many diseases and presents several unique features which make it especially prone to occupational disease. It is more usually exposed to injurious agents than any other organ or region of the body. It is usually unprotected except when masks are worn. The function of the oral cavity as the port of entry of food and its participation in mastication, speech and laughter keep it open a considerable part of the time in spite of the readiness of the lips to close it.

Ingestion and inhalation of foreign substances that tend to stagnate and collect within the oral cavity lead to an accumulation of irritants of a chemical, physical or bacterial nature, especially along the gingival crevices about the teeth. The gingival portion of the oral mucosa, because of its frequent exposure to irritation, is in a constant subclinical state of disease and often shows microscopic and macroscopic responses of inflammation.

The oral cavity is a moist chamber which offers a warm, nutritive and protected environment for bacteria and infection. Nevertheless, wounds in the mouth are not commonly infected because of the rich blood and lymph supply and the bacteriostatic action of the saliva. Once this resistance is lowered, however, the vulnerability of the oral tissues comes into play. While the rich blood and lymph supply promotes ready and relatively rapid absorption, it also brings to the oral tissues whatever systemic influences may obtain elsewhere, whether they are physiologic or pathologic in their effect. Thus the soft tissues as well as bone are vulnerable to both local and systemic irritations. This is in contrast to the exposed enamel and the underlying dentin, which, because they are both avascular and acellular, are affected only by local factors.

5. Standard Bodyparts Adjustment Guide. Insurance Statistical Service of North America. Chicago, 1941.

The different types of structure ranging from the oral mucosa to the highly specialized and mineralized enamel account for the rich variety of response that is displayed in the oral cavity (fig 1). It must be pointed out that the regenerative power of the gingivae is high and that the introduction of oral hygiene and the removal of irritations result in a ready return to health.

The oral structures may be divided into the hard and soft parts.

HARD STRUCTURES

While the enamel, dentin, cementum and bone are all hard, calcified structures, they differ significantly in their response to injury and their capacity to repair.

Enamel—This structure is formed in a protected environment within the bony crypts of the jaw and during its period of formation and calcification responds

Fig. 1—Diagrammatic representation of the dental tissues (from Noyes, Schour and Noyes, courtesy of Lea & Febiger).

very delicately to changes in general metabolism, particularly those in calcium metabolism. When, however, the enamel has been completed and has appeared in the oral cavity, it has lost its formative organ and therefore its power of growth. It can then be affected only by local environmental agents.

The enamel of the erupted tooth is exposed to the oral fluids and environment. Its response to injury is mechanical or chemical and entirely passive. Being without cells, blood or lymph supply, the enamel is incapable of inflammatory reaction. Mechanical trauma does not result in increased cornification as in the skin but in physical wear, the type of trauma determining the pattern of wear. The action of acid is very effective, since the mineral salts which constitute nearly 100 per cent of the enamel dissolve readily even in a mildly acidic medium.

The ready response of enamel to acids makes it vulnerable to decalcification. A smooth surface of enamel that is clean and bacteria free will not decay. However, the pits and fissures and the interproximal areas of the teeth are rarely free from debris and therefore are favorable regions for bacteria and acid fermentation and dental caries.

Dentin—This structure is also noncellular and avascular but can transmit through its tubules stimuli from the enamel surface to the pulpal cells. The latter, in turn, respond by forming a typical dentin (secondary dentin) which is often followed by sclerotic changes in the dentinal tubules and matrix.

Cementum—The cementum covers the root of the tooth and is normally well protected by the investing structures. It does not respond to external local factors unless it has become exposed by the recession of the gingivae and pocket formation. Normal cementum, like bone, undergoes continuous formation throughout life, permitting continuous reattachment of newly formed periodontal fibers. Unlike bone, however, resorption of cementum is a pathologic condition. Unfavorable systemic conditions may destroy the vitality of the cementum and lead to detachment of the periodontal fibers by cementum resorption.

Alveolar Bone—The alveolar bone, in contrast to the enamel and dentin, undergoes continuous apposition and resorption and consequently is susceptible of repair. It grows throughout life in adjustment to the continuous eruption of the teeth. The proximity of alveolar bone marrow to chronic gingival inflammation makes it more vulnerable to osteomyelitis. Involvement of the jaw bone is secondary to that of the alveolar bone and usually occurs much later.

SOFT STRUCTURES

The soft structures may be divided into those immediately associated with the teeth and those found in the remainder of the oral cavity.

The soft dental structures are the pulp within the tooth, the periodontal membrane surrounding the root and the gingivae, which cover the alveolar bone and invest the necks of the teeth.

The Gingivae—This tissue constitutes that portion of the oral mucosa which rests on bone chiefly alveolar bone, and has therefore been called alveolar mucosa. Its attachment to the underlying bone and its protection by a superficial cornified layer of epithelium give it a firm resistant texture. The sensory nerve supply of the gingivae is limited. Injuries to the gingivae are therefore relatively less painful and often are neglected.

The gingivae have rightly been called the gateway to oral health. They are more exposed to chronic irritation than any other portion of the oral cavity and are therefore in a state of chronic inflammation. This subclinical state of inflammation is associated with the presence of many plasma cells in the connective tissue and is so common that it may be regarded as characteristic of the gingivae.

The gingival crevice which arises during the separation between the gingival epithelium and the tooth coincident with the continuous eruption of the tooth is an especially vulnerable region. This favors the formation of a pocket with its sequelae of regressive injuries to the investing and supporting dental structures.

The Oral Mucosa—The soft oral structures that are not immediately associated with the teeth are the freely movable portion of the oral mucosa, the lips, the tongue and the salivary glands. The oral mucosa is not covered by a cornified epithelial layer and is quite sensitive.

The color of the oral mucosa is a transparent red, in contrast to the opaque pink coloration of the gingivae,

TABLE 1—Oral Manifestations of Occupational Disease According to the Structure Affected

Mode of Action	Structure Affected	Etiologic Agent	Manifestation
Local	Tooth { Enamel and dentin	Dust Dust Prehension of instruments Acid Sugar	Staining Abrasion Abrasion Decalcification Caries

+ Systemic	Lips	Low humidity dust Inhalation carbon monoxide Tar	Dryness fissure Cheilitis leukoplakia Coloration of lips Carcinoma
Oral cavity	Oral mucosa	Dust Chemicals	Pigmentation Stomatitis
	Tongue	Food tasters	Anesthesia Paresthesia
	Salivary glands	Mercury compounds X ray radium Increased intraoral pressure	Ulceration Pyorrhea Necrotoma Pneumotocle

in which the rich capillaries are not so readily seen because of the presence of the opaque cornified layer of epithelium.

Injuries to the gingivae and oral mucosa heal more rapidly than do similar injuries elsewhere. The reason for the more rapid rate of healing may be found in the high vascularity of these tissues, their rich lymph supply and the bacteriostatic quality of the saliva.

PATHOLOGY

Basically, every oral manifestation of occupational disease is a reaction following the exposure of the oral cavity or its component parts to external noxious agents which act either locally or systemically (table 1).

The various pathologic end results may be classified (table 2) in the following order: (a) abrasion, (b) decalcification, (c) caries, (d) pigmentation of enamel and gingivae, (e) inflammation, (f) circulatory disturbances, (g) degeneration and (h) neoplasm.

ABRASION, DECALCIFICATION, CARIES

Because of our child labor laws, few engage in work while their teeth are still growing. Developmental defects such as enamel hypoplasia or mottled enamel, therefore, do not occur as a result of occupational hazards. However, breast feeding by mothers working with cryolite has resulted in the mottled enamel of their children.⁶ The hardness and chemical composition of enamel and dentin predispose them to the pathologic processes of abrasion, decalcification and dental caries, which are uniquely characteristic of the teeth alone.

Abrasion—Abrasion or excessive wearing of enamel and dentin is dependent on some abrasive acting for a relatively long period. Localized abrasion is found in occupations in which the teeth are used for the holding of various objects. Thus seamstresses will show fine notches on the incisal edge of their anterior teeth as a result of biting thread or holding the needle between the teeth (fig 2A). Larger areas of wear are seen in the teeth of carpenters, shoemakers and upholsterers, who hold tacks or nails in the mouth (fig 2B). This is not surprising when one considers the fact that a worker in the automobile upholstery business can place 8,000 tacks a day.⁷ In glass blowers, players of wind instruments and policemen a definite pattern of wear on the teeth will result, depending on where the pipe, instrument or whistle is placed (fig 2C).⁸ These stigmas are permanent because the enamel and dentin are not susceptible of repair, as are bone and soft tissue. The holding of foreign bodies in the mouth may also lead to fractures of the enamel and traumatic effects on the periodontal structures.

TABLE 2—Oral Manifestations of Occupational Disease According to the Pathologic Process

Pathologic Process	Structure Affected	Etiologic Agent	Diagnosis
Excessive wear	{ Enamel and dentin	{ Instruments of prehension nails thread whistle Cement sand	{ Localized abrasion Generalized abrasion
		Acids	Decalcification
Chemical reaction	{ Enamel and dentin	Sugar	Caries
Bacterial action fermentation	{ Enamel and dentin	Mercury Carbon metals	Stained enamel Pigmentation of oral mucosa
Pigmentation	{ Direct contact (physical) Via blood stream ((chemical))	{ Enamel Oral mucosa Gingivae Lips oral mucosa	Lead mercury bismuth Carbon monoxide Heavy metal sulfide line of gingivae Cherry red lips (carbon monoxide and hemoglobin)
	Lips	{ Low humidity heat cold trauma acid metals	Cheilitis
Inflammation	Oral mucosa gingivae	{ Heat cold trauma mercury alkali acid	Stomatitis gingivitis
	Periodontal membrane	Mercury flour	Periodontitis
	Alveolar bone jaws	Arsenic mercury phosphorus radium	Osteomyelitis
Circulation	{ Gingivae and mucous membrane	Benzene variations in atmospheric pressure	Hemorrhage
Degeneration	{ Oral mucosa and lips Alveolar bone and jaws Salivary glands	Mercury acid Radium X ray	Ulceration Osteonecrosis
		Radium X ray	Necrosis (necrotoma)
Neoplasm	Oral mucosa	Hot coffee tea Irritation	Leukoplakia
	Lips	{ Electricity out door exposure tar	Leukoplakia carcinoma of lip

Dust of abrasive quality, such as cement or sand, will collect on the occlusal surfaces of the teeth and produce generalized abrasion. Abrasive powders and pastes used to clean the teeth can also cause abnormal wear.

7 In a recent decision of the Wisconsin State Industrial Commission the employer was ordered to pay an upholsterer the cost of restorations necessary to correct the dental disability resulting from holding tacks between the teeth.

8 Kraus M. Ueber Veränderungen an den Zähnen als besondere Folgen beruflicher und gewerblicher Beschäftigung. Zentralbl. f. Gewerbehyg. 3: 127-129 (May) 1926. Herrmann W. Ueber die im Glasblasberuf vorkommenden Schädigungen und Erkrankungen des Mundes und der Zähne sowie deren Prophylaxe und Therapie. Ibid. 7: 193-197 (July) 218-223 (Aug.) 1930.

A distinction, however, should be made between abrasion and attrition. The latter is the physiologic wear of teeth with age.

Decalcification—Decalcification of enamel and dentin, a local chemical action, is seen following exposure to acids among workers in explosive factories or acid dippers⁹ (fig. 3). The acid fumes deposited on the exposed portions of the teeth react with the enamel, which is completely calcified, and decalcification results. The earliest reaction consists of a superficial decalcification of the enamel of the labial surface of the tooth which is exposed most. Mastication and tooth brushing wear off the partially decalcified areas and produce flat smooth surfaces. The normal luster is lost. Since it is less exposed to the acid fumes and is protected by more saliva, the lingual surface is preserved longer, and the crown takes a sloping form. The crowns of the teeth disintegrate with prolonged exposures.

Similar action on the teeth is seen in medical practice in patients with protracted vomiting in which the hydrochloric acid from the stomach decalcifies the enamel. In these cases, however, the lingual surfaces of the teeth are affected first. Patients receiving hydrochloric acid for achlorhydria should therefore be cautioned to use a glass drinking tube to avoid the decalcification of the enamel.

Fig. 2—Abnormal local wear of teeth (abrasion) due to repeated (a) biting of thread (scamstress), (b) holding nails between teeth (carpenter) and (c) holding pipe between teeth (glass blower).

It must be pointed out that it is only by this local means that calcium can be removed from the tooth. The enamel and dentin cannot serve as a storehouse for calcium, since they are acellular and avascular, and calcium withdrawal does not occur even during severe upsets in calcium metabolism (hyperparathyroidism) or in pregnancy, as is commonly believed. In the bones, however, resorption may take place, and in that manner the need for calcium may be supplied.

Dental Caries—Dental caries is the third local process that is uniquely characteristic of the teeth. A high incidence of tooth decay has been reported among workers who are exposed to sugar dust¹⁰. The latter tends to be deposited along the labial gingival surfaces of the crown where it stagnates and induces abnormal fermentation and, with the aid of bacteria, acid production. The resulting caries first assumes the form of a demilune and spreads over the surface of the crown in a characteristic manner (fig. 4). Rose¹¹ examined the caries

incidence in different occupations and found the highest incidence among sugar bakers. A carefully controlled study of the problem of so-called "sugar caries" is very much needed. Abrasion, decalcification and caries are irreversible destructive processes on the teeth, which are not subject to self repair. Consequently, all efforts should be made to prevent their occurrence.

PIGMENTATION OF ENAMEL

Characteristic staining of enamel is observed among workers exposed to metal dusts which lodge on the teeth¹². Thus copper workers show a green and silver workers a black staining of deposits at the necks of the teeth (fig. 5). Staining may also be seen on the teeth of patients who are receiving iron compounds and are not using a glass drinking tube to prevent contact. In contrast, the green stain which frequently is seen associated with gingival mucous plaques in children is due to chromogenic bacteria. These stains may be removed by proper cleansing of the teeth.

PIGMENTATION OF GINGIVAE

The exogenous pigmentations of occupational origin that become effective after absorption and circulation in the blood stream should be distinguished from the endogenous brown melanin of the gingivae that is seen normally, especially in the Negro.

The location of the pigment varies with its nature and method of absorption or deposition. Melanin is found in the basal layer of the epithelium. The coal or metal dusts accumulate on the surface of the gingivae or penetrate various levels of the epithelium and sometimes even the dermis. The sulfides of heavy metals, on the other hand, are found only in the dermis but become nevertheless, clinically visible as lines about the gingivae (fig. 6). Pigmentation in other parts of the oral cavity is not common.

Gingival Lead Line—Pigmentation of the gingivae is often but not always observed following the ingestion or inhalation of the heavy metals—lead, bismuth or mercury. This was first described by Grisolle¹³ in 1835. In addition, a similar black discoloration in the mucosa of the colon and lower portion of the small intestine was first observed by Tanquerel¹⁴ in 1839. Lead alone is known to be a potential hazard in about one hundred and fifty specific occupations (table 4).

The pigmentation when present tends to be sharply localized about the gingival margin and gives rise to the so-called heavy metal line. The mere ingestion or inha-

tion of lead is not sufficient to produce a lead line. Another essential factor is the presence of poor oral hygiene as manifested by the presence of calculus or debris and of chronic gingivitis. Lead absorption does not cause inflammation but rather inflammation brings

Fig 3—Decalcification of enamel by acid fumes. The labio-lingual portions of the teeth which are most exposed are affected first

out the lead line, which thus acts as an indicator of the presence of gingivitis. It follows, therefore, that in the clean, healthy mouth a lead line will not occur in spite of lead intoxication.

Clinical Appearance. Goadby¹⁵ has distinguished several degrees of lead lines.

1 Faint, mottled patches of bluish black at the extreme edge of the gum, often affecting only single teeth and best seen with a hand lens.

Fig 4—Sugar caries as seen in pastry bakers and candy makers (after Krause). The labio-lingual areas of the teeth are attacked first

2 A blue-black line, finely penciled, following the whole of the gum margins, increasing in depth to positions where inflammation of the gums is more pronounced.

3 A blue-black line at the margin of the gums which fades imperceptibly into the rest of the gingival tissue, the upper or free margin of the gum being the most intensely stained. Patches of black or blue-black pigment are also found on the cheeks, usually opposed to large patches of tartar.

Mechanism of Action and Histologic Analysis. Following its inhalation or ingestion, the lead reaches the blood stream, where it is present in colloidal solution as tertiary phosphate. The lead is then stored in different parts of the body, especially in bone. Histologic studies show that black lead sulfide granules are absent in epithelium but are found in the histiocytes of the connective tissue.¹⁶ Hydrogen sulfide formed during the protein decomposition in food debris and coincident with the cellular destruction and increased metabolic activity in gingivitis penetrates the epithelium and unites chemically with the heavy metal in the connective tissue adjacent to the blood vessels to form a black precipitate of lead sulfide. Accumulations of the granular lead sulfide give the characteristic clinical lead sulfide line.

Siegmund and Weber¹⁷ found the earliest effect in the adventitial cells near the blood vessels of the con-

Fig 5—The superficial staining of the crowns of teeth in workers who practice poor oral hygiene and are in contact with metallic dusts. The coloration varies with the particular metal (after Krause).

nective tissue papillae. These cells, following the laws of vital staining, store the lead which was in solution in the circulating blood in very fine granules. The latter are gathered into larger particles, resulting in the enlargement of the histiocytes, which are also found in the loose connective tissue. In later stages, the lead granules are seen in fibroblasts and in the intercellular substances. Finally the fibrils are densely impregnated with the black lead sulfide granules, and their deposition occurs also in the basement membrane.

All material that was available for their study showed gingivitis, as evidenced by cellular proliferation and exudate and a considerable thickening of the epithelium. Thus gingivitis was the condition that made possible the reception and deposition of the lead, and these investi-

17 Siegmund, H., and Weber, R. Pathologische Histologie der Mundhöhle. Leipzig: S. Hirzel, 1926.

gators therefore regarded lead pigmentation as a special case of vital staining in the region of inflammation. Capillarymicroscopic studies of heavy metal lines have confirmed the microscopic results.¹⁸

The Importance of Oral Hygiene in the Production of the Lead Line—Goadby¹⁹ in a careful study of lead poisoning was unable to recognize a lead line in persons with clean mouths free from gingival inflammation. Further evidence of the role of gingivitis in the production of the lead line is seen in the fact that lead lines are not found in infants or edentulous patients. The relationship between lead exposure, oral hygiene and the formation of the lead sulfide line may be represented in the following formulation:

$$\begin{array}{ccccc} \text{Lead} & & \text{Hydrogen sulfide} & & \\ \text{exposure} & \times & \text{elaborated in inflamed} & = & \text{Sulfide} \\ & & \text{gingival areas} & & \text{lead line} \end{array}$$

Thus the lead exposure alone is not sufficient to produce a lead line. The presence or absence of the latter is therefore not an accurate index of lead poisoning unless one takes into consideration the state of oral health.

Fig. 6—The heavy metal (sulfide) line in the gingivae

Differential Diagnosis—The lead line was selected as representative of the "heavy metal" lines seen in the gingivae. The mercury and bismuth lines arise in a similar manner. It is difficult to differentiate them. They should not be confused with the cyanotic bluish tinge seen in the gingival margin in suppurative gingivitis or periodontitis or with the surface stains of the enamel adjacent to the gingivae.

INFLAMMATION

Enamel, Dentin and Pulp—Enamel is nonvital. It is avascular and acellular. Consequently trauma and irritation do not elicit an inflammatory reaction, which would be expected in living tissues. The same is true of dentin. When injury of the enamel and dentin has been sufficiently severe to irritate the pulp, the latter will respond by formation of secondary dentin, hyperemia or inflammation. In the event of inflammation, death of the pulp usually follows. The reason for this is that the pulp is surrounded by the calcified, non-

yielding walls of dentin and the narrow apical foramen acts as a bottleneck, limiting the arterial blood supply but retarding the venous return and causing self strangulation.

Gingivae—A mild subclinical gingivitis is present in most persons. This condition may, however, be aggravated by various occupational agents that act in the oral cavity. It is likely that many stubborn cases of gingivitis which do not respond to the accepted treatment may be due to some persistent occupational factor.

Lips and Oral Mucosa—Cheilitis may result from exposure to dust, low humidity and chemical agents. A reaction has been reported following exposure to volatile oils.²⁰ Lipstick dermatitis is usually caused by the action of the perfume.²¹

The various acids (hydrochloric, hydrofluoric, sulfuric and nitric) affect the oral cavity by direct contact with the spray or fumes. Ulceration and inflammation of the soft tissues of the mouth with some hemorrhage and decalcification of exposed calcified structures are the common manifestations. Gases like ammonia, chlorine and bromine have a local irritating action, ammonia vapor leading to reddening and bleeding of oral mucosa.

The traumatized tissue may become secondarily infected because the oral cavity is an excellent incubator for bacteria. Bacteria today are seldom the primary etiologic agents of lesions of the mouth. Glanders and hoof-and-mouth disease are rarely seen but should be remembered in the differential diagnosis. Actinomycosis, according to recent evidence, is endogenous in the oral cavity and occurs without contamination from the outside.²² The specific bacterial etiology of "Vincent's infection" is increasingly being challenged. The fusiform and spirochetel organisms are probably only secondary invaders and are not direct and important factors.²³

Bone—The alveolar processes and jaws are frequently the first structures affected. This is exemplified particularly in yellow phosphorus poisoning in which the 'phossy jaw' is a characteristic finding,²⁴ in mercurial poisoning in which the teeth become loose and are eventually exfoliated, and in radium poisoning, which was first diagnosed because of toxic effects on the jaw bones.

Alveolar bone in the adult has a lower threshold to infection than other bone because of the surrounding infection associated with gingivitis, the continued stress and strain of mastication and its more active growth and metabolism. In addition, alveolar bone may be exposed to phosphorus, mercury or radium compounds through three routes—ingestion, blood stream and salivary gland secretion (fig. 10)—whereas other bones are exposed only through the blood stream.

In the early stages only the alveolar bone is affected. In mercury poisoning the disease process may be limited to the alveolar portion of the mandible and maxilla and rarely extends much beyond the level of the apexes of

the teeth.¹⁴ In the later stages, however, the osteomyelitis may include a greater portion of the jaws and is followed by sequestration. Consequently workers exposed to mercury, phosphorus or radium compounds, or patients receiving mercury bismuth or radiation therapy in the maxillofacial region, should maintain the oral cavity in the optimum state of health. The soft tissues and teeth should be kept clean so that the noxious agents will not accumulate and be absorbed and so that the gingivae will remain as free of infection

areas of gingivitis and periodontitis. According to Siegmund and Weber,¹⁷ mercurial necrotic stomatitis begins with the deposition of metallic mercury in the capillary endothelium and adventitial cells leading to circulatory disturbances, stasis and diapedesis. This is followed by tissue necrosis, bacterial invasion from the area of gingivitis and finally destruction of the tissue. Gross examination reveals inflammation of the mucous membrane. The gingivae are tender, soft, swollen and receded. Mercury sulfide, as in lead and bismuth

TABLE 3—Oral Manifestations of Occupational Disease According to the Etiologic Agent

Etiologic Agent				
Physical State	Principal Action	Specific Factor	Occupation	Possible Oral Manifestations
Solid	Physical	Instruments for percussion	Cobblers, carpenters, glass blowers, musicians (wind instruments), stonemasons	Localized abrasion
	Chemical	Tar	Fishermen, asphalt and coal tar workers, pavers, pitch roofers, wood preservers	Stomatitis, carcinoma of lip and mucosa
	Physical	Inorganic: Copper, iron, nickel, chromium, coal, etc.	Bronzers, cement workers, electrotypers, grinders (metal), miners, stone cutters	Staining of teeth, pigmentation of gingivae, generalized abrasion, calculus, gingivostomatitis, hemorrhage
Dust	Physical	Organic: Bone charcoal, sawdust, flour, tobacco	Bone charcoal, flour, sawmill, textile and tobacco workers	Staining of teeth, pigmentation of gingivae, generalized abrasion, calculus, gingivostomatitis, hemorrhage
		Inorganic: Arsenic	Chemical workers, electroplaters, metal refiners, rubber mixers, lead smelters, insecticide makers, Bismuth handlers, dusting powder makers	Necrosis of bone
	Chemical	Bismuth		Blue pigmentation of gingivae, oral mucosa, gingivostomatitis
		Chromium	Aniline compound, chrome, photographic and steel workers, blue printers and rubber mixers	Necrosis of bone, ulceration of oral tissues
		Fluorine	Cryolite workers	Osteo sclerosis
Liquid	Chemical	Lead	Electrotypers, insecticide and storage battery makers, lead refiners, printers, rubber compounders	Blue black pigmentation of gingivae, gingivostomatitis
		Mercury	Bronzers (gun barrels), battery and paint makers, dentists, detonators, explosive and mercury salts workers	Gingivostomatitis, osteomyelitis, pyaemia
	Physical	Phosphorus (white, yellow)	Brass founders, match factory, phosphor bronze workers, fertilizer and fireworks makers	Gingivostomatitis, ulceration of oral tissues, osteomyelitis
		Organic: Sugar	Refiners, bakers, candy makers	Caries
		Hot food (coffee, tea, soup)	Tasters	Stomatitis, leukoplakia
Gas	Chemical	Aniline	Aniline, coal tar, explosive workers, painters, tannery workers, vulcanizers	Blue coloration of lips and gingivae
		Benzene	Coke oven and lacquer workers, dry cleaners, vulcanizers, smokeless powder makers	Hemorrhage from gingivae, stomatitis, blue coloration of lips
	Physical	Cresol	Coal tar, rubber tar, distillery and surgical dressing workers, disinfectant makers	Stomatitis
		Wine and liquor	Tasters	Anesthesia and paresthesia of tongue
		Atmosphere: Increased pressure	Divers, caisson workers	Bleeding from gingivae
Ray	Chemical	Decreased pressure	Aviators	Bleeding from gingivae
		Acids: H ₂ SO ₄ , HNO ₃ , HCl, HF, Amyl acetate	Acid and cartridge clippers, petroleum refiners, explosive and gun cotton workers, galvanizers, Alcohol distillery, explosive shell, smokeless powder and shoe factory workers	Bleeding stomatitis, decalcification of enamel and dentin, Stomatitis
	Physical	Aerolein	Bone grinders, lard soap, linoleum makers, varnish boilers	Stomatitis
		SO ₂ , NH ₃ , BR, Cl	Acetylene dye, photographic film, phosgene makers, sugar refiners, refrigerating plant, disinfectant laundry workers	Stomatitis
		CO, CO ₂	Miners, smelters, gasoline motor workers	Coloration of lips (cherry red, blue)
Ray	Physical	Radium, X-ray	Technicians, watch dial painters, research men	Gingivitis, periodontitis, osteomyelitis and necrosis, xerostomia, osteo-sclerosis
		Actinium	Sailors, fishermen	Carcinoma of lip

as possible. Carious and pulpless teeth that are beyond treatment should be extracted before the individual is exposed. Observance of oral hygiene will prove to be a valuable safeguard because surgical treatment of the jaws is hazardous in such cases.

MERCURY POISONING

Mercury poisoning may be manifested in all the soft tissues of the oral cavity as well as in bone (fig. 7). The usual accompanying symptom is an exacerbation of preexisting oral disease. The stomatitis arises in

poisoning, is deposited in the subepithelial tissue and is manifested as a blue-black line on the gingivae around the teeth.¹⁵ The teeth are loose and the swollen tongue shows the impressions of the teeth. Mechanical injuries of mastication, friction of the tongue on the teeth and irritation are factors in ulceration. The excess salivation is believed to be due to a stimulation of the secretory nerves by mercury.²⁰ Many of these symptoms were described by Ramazzini¹ in 1713 in mercury miners in Spain.

Mercury compounds are potential hazards in more than one hundred occupations today (table 4). While the occurrence of mercury poisoning in hatters and fur-cutters was reported as early as 1859,²⁷ the mercury hazard among these workers has been eliminated only recently.²⁸

TABLE 4—*Oral Manifestations of Occupational Disease According to the Occupation*

Occupation	Active Agent	Possible Oral Manifestation
Abrasive powder workers	Dust	Generalized abrasion of teeth; calculus
Acid dippers	Fume	Decalcification of teeth; stomatitis
Arsenic roasters and handlers	Arsenic	Osteomyelitis and necrosis of mandible
Aviators	Variation in atmospheric pressure	Hemorrhage from gingivae
Bakery workers	Flour sugar	Calculus; periodontitis; caries
Candy workers	Sugar	Caries
Carpenters	Nails	Localized abrasion of teeth
Coal tar contacts	Tar	Carcinoma
Cryolite workers	Fluorine	Osteosclerosis
Electrotypers	Lead	Lead line gingivae
Explosives workers	Benzene	Hemorrhage from gingivae
Garment workers	Chemical dyes for color bodies in mouth	Stomatitis; abrasion of teeth
Glass workers	Hydrofluoric acid	Decalcification; pneumatocelic abrasion
Lead workers	Lead	Lead line gingivae
Metal workers	Dust (iron, copper, chromium)	Staining; of enamel; pigmentation of oral mucosa
Mercury workers	Mercurial compounds	Gingivitis; periodontitis; ulcerations; pyorrhea; osteomyelitis
Photographic workers	Mercurial compounds; chromium	Gingivitis
Polishers and blasters	Dust	Abrasion; pigmentation
Stoneworkers	Dust	Abrasion; gingivitis
X-ray technicians	X-ray (radium)	Xerostomia

In a recent examination of fur-cutters for mercury poisoning, significant findings were observed in the supporting structures of the teeth.²⁹ However, the incidence of caries was about equal in the two groups. The enamel and dentin, which are nonvital, were naturally not affected by the mercury compounds.

Workers using an antifouling mercurial paint to protect hulls of warships from growth of aquatic life have shown mercurial poisoning. The most common disorders were tremor of the hands and gingivitis. The chief complaints were hoarseness and fatigue, sore gums and bad taste.³⁰

CIRCULATORY DISTURBANCES

Bleeding gingivae may act as an indicator of local or systemic disease. Local causes are usually deposition of calculus and gingivitis. Variations in atmospheric pressure to which divers, caisson workers and aviators are subjected may cause hemorrhage, especially if gingival irritation is already present.

Gingival bleeding, ulceration and necrosis of the maxilla may result from exposure to benzene,³¹ as among vulcanizers, coke oven and smokeless powder workers (fig 8). Benzene has a slow and insidious action. It has a direct effect on the bone marrow,

causing an aplastic anemia. Bleeding from the gingivae, of course, is frequently seen in blood dyscrasias and vitamin C deficiency.

Carbon monoxide, the most common poisonous gas in industry today, unites with hemoglobin and gives a cherry red color to the blood.³² Wherever the blood is close to the surface, as in the lips, the characteristic coloration is seen. In aniline poisoning the lips are blue.

DENEGRATION

The exposure of workers to radium has resulted in the destruction of the osteogenic properties of bone and in necrosis of the mandible. Xerostomia has occurred also following changes in the secretory epithelium of the salivary glands.

Ingestion of radium compounds by watch dial painters who point the brush with the lips was common several years ago.³³ Those working with radium and X-rays for technical and research purposes are also exposed to the radiations. The symptoms appear after a variable latent period. The gingivae become inflamed, ulcerated and painful and a foul breath is present. This may be followed by gingival recession, periodontitis and loss of alveolar bone. The teeth become loose and show resorption of the root. In the later stages, osteomyelitis, osteonecrosis and osteosclerosis of the jaws occur with the loss of teeth and the formation of sequestrums (fig 9). In radium poisoning the symptoms usually occur early in the oral cavity.³⁴ The first case was diagnosed in 1924 because of oral complaints.³⁵

It is therefore important that adequate precautions be taken by those working with radium and X-rays for technical and research purposes so that they will not be exposed to the radiations.

Fig. 7—Mercurial stomatitis (after Koelsch). Note the gingival swelling and the ulcerations.

NEOPLASM

The reported incidence of carcinoma in the oral cavity is relatively high. The oral cavity is subjected to more irritation than many other parts of the body. In addition,

tion, its ready accessibility permits earlier and more frequent diagnosis

Outdoor workers, particularly sailors, exposed to the actinic rays, may develop carcinoma of the lip. This occurrence is further enhanced in sailors and fishermen by using tar. The latter frequently hold a tarred needle

Fig 8—Gingival hemorrhage in benzene intoxication

between the lips when repairing fish nets³⁶. It has been reported that the incidence of carcinoma of the skin and lip of sailors in the United States Navy is eight times as high as the normal incidence³⁷. Carcinoma of the lip and cheek is found also in pitch workers³⁸. Carcinoma occurs in the lower lip of white males but seldom in the upper lip, and it is found less often in females and in Negroes³⁹.

Carcinoma of the oral cavity is frequently preceded by leukoplakia. This is found particularly in cases in which chronic and recurrent irritation plays a role, such as in food-tasters (heat), glass-blowers (heat and trauma) and cobblers, whose oral structures are constantly irritated by nails held in the mouth⁴⁰.

ETIOLOGY

An analysis of the various etiologic agents which are responsible for oral occupational disease shows that their harmful effects depend on their specific chemical, physical or bacterial nature (table 3), their physical state and their mode of entry (fig 10).

THE SPECIFIC NATURE OF THE ETIOLOGIC AGENT

Chemical Agents—Inorganic Group The chemical agents, inorganic and organic, are the principal causes of occupational disease. The metals and their compounds comprise the inorganic group. Until recently metal poisoning was considered as confined to lead, mer-

cury and arsenic. But with the development of specific alloys the toxic properties of all metals have demanded inquiry. Frequently a new substance has been used without prior knowledge of its effects on the body. While certain pure metals may be harmless, their compounds or acid salts may be poisonous. Thus the hazard offered by industry is seldom that of a single metal but rather of a combination of metals⁴¹.

Organic Group The field of synthetic organic chemistry has expanded so rapidly in recent years that it is important to keep informed as to the effects of the new products used in industry not only in the oral cavity but in the entire body⁴².

Physical Agents—While the chemical agents cause the majority of oral occupational diseases, physical agents are also of importance. They act locally on both hard and soft tissues. Dust, thread, nails or other solid objects kept between the teeth may produce abrasion of enamel and dentin. There are only a few studies on the influence of atmospheric temperature and humidity on the dryness of the oral mucosa⁴³. Variations in atmospheric pressure to which aviators and divers are subjected may produce bleeding, especially if gingivitis is already present. Because of increased intraoral pressure (musicians of wind instruments and glass-blowers), air will sometimes enter Stenson's duct and the various lobes of the parotid gland and cause a chronic swelling⁴³ (pneumatocoeles). The tasting of hot foods may irritate

the oral tissues and result in leukoplakia. The possible effects of radiation from radium and x-rays and of the actinic rays have already been described.

Bacterial Agents—With the rapid strides made in bacteriology, public health and preventive medicine, occupational hazards of a bacterial nature have become rare. Bacterial infection directly related to occupation is of primary concern when animals or animal products are handled. Anthrax, hoof-and-mouth disease and glanders are less often seen today because of the preventive measures taken.

THE PHYSICAL STATE OF THE ETIOLOGIC AGENT

The smaller the size and the greater the state of dispersion of the particles of which the etiologic agent is composed, the greater the surface area and the more severe the effects. Table 3 shows the range of the physical state from solids to rays.

The harmful oral effects produced by dusts of organic or inorganic nature range practically through the entire gamut of pathologic lesions¹⁴ and are enumerated and presented in table 5.

Mode of Entry—There are three channels by which the noxious agents can enter the system—inhalation in the case of gases, fumes or dust, ingestion in the case of solids or liquids, and, much more rarely, absorption directly through the skin in the case of mercury and benzene (fig 10).

These modes of entry are significant because they determine the severity of the effects. Local effects are illustrated by the direct action of dusts or acids in the

monoxide or aniline alter the constituents of the blood and produce a cherry red or blue coloration of the oral mucosa, while lead and mercury are merely transported through the blood stream or saliva into the oral tissues.

OCCUPATIONAL DISTRIBUTION

For each occupation in which oral disease occurs there is usually one outstanding etiologic agent, although not infrequently two or more agents may be acting

TABLE 5—The Various Effects of Dust on Oral Structures

Local or Systemic Action	Mode of Action	Oral Effects
Through local action	Accumulation on surface (metals)	Staining of enamel, pigmentation of oral mucosa
	Coarctation (coal cement)	Abrasion
	Fermentation (sugar)	Cariates
	Nidus for pulpitis (flour)	Caries
	Irritation	Gingivitis, cheilitis
Through blood stream	As Hg, Pb (+ infection)	Osteomyelitis of jaws
	Mercury compounds (+ skin lesions)	Gingivostomatitis
	Heavy metals (+ hydrogen sulfide)	Heavy metal line in salivary

together. In table 4 some of the important occupations have been selected which illustrate the variety of oral lesions that may occur.

For the purposes of this report no attempt was made to present an exhaustive list. A detailed comprehensive enumeration of the occupations and their characteristic oral hazards, however, would serve as a useful guide to industrial physicians and dentists.

THE IMPORTANCE OF ORAL HYGIENE

Oral manifestations of occupational origin are readily predisposed and aggravated by neglect of oral health, and the problem of prevention of oral occupational hazards must be attacked both by improving the working conditions and by establishing and maintaining oral health.

The presence of the etiologic agent alone is not enough to cause oral disease. The general and the oral health of the patient are equally important.

An analysis of the various oral manifestations of occupational disease reveals the recurrent theme that in the presence of optimal oral health these manifestations are minimal or entirely absent. The significance of oral health in preventing oral disease is indicated in the following formulation:

$$\begin{array}{ccccc} \text{Etiologic agent} & & & & \text{Oral} \\ \text{of} & & \times & \text{Poor} & \text{health} \\ \text{occupational origin} & & & \text{oral} & = \text{Oral} \\ & & & \text{health} & \text{occupational} \\ & & & & \text{disease} \end{array}$$

Thus oral health is more than an additive or reducing factor in the production of oral occupational disease, it is a controlling factor. The lead line or mercurial stomatitis to cite a few examples, is prominent, mild or absent depending not only on the dose and intensity of the etiologic agent but to an equally significant extent on the degree of oral health. Complete elimination of poor oral health gives this factor a value of 0 and therefore prevents oral occupational disease just as tubercle bacilli alone in the healthy person will not produce tuberculosis.

Experimental evidence of this relationship has been presented by Goadby,¹⁵ who was able to control the lead line at will by modifying gingival health. In an investigation in which cats were exposed to inhalation of lead dust and developed lead poisoning, Goadby found no lead line. He modified his experiment by

Fig. 10—Diagram showing modes of entry of dusts, fumes and gases and their local and systemic routes to the oral cavity.

oral cavity. The systemic effects act by absorption into the blood stream through the lungs, alimentary system or skin.

Ingested materials are less harmful than inhaled substances because in the former instance they pass through the liver before gaining entrance into the systemic circulation. Once these substances are in the blood stream their mode of action may vary. For example, carbon

44. Weinberger, Walter. Ueber gewerbliche Schädigungen im Bereiche der Mundhöhle. Ztschr. f. Stomatol. 32: 196-201, 1934.

placing ill fitting gold crowns about several teeth of the ummils, which were then exposed to lead. In a very short time and before any other signs of lead poisoning definite blue lines appeared in the inflamed gingivae about the crowned teeth.

The scope of this paper does not include a consideration of treatment. However, it is recognized that prevention is the most important and efficient method of treatment. Prevention can be effected by proper working conditions and by strict oral hygiene. The latter should begin before admission into a particular occupation and should continue throughout the course of the employment period. Moreover the training for a particular occupation should include attention to the general health of the worker and the particular health of those parts of the body which are exposed to oral occupational hazards. Oral hygiene is an essential part of industrial hygiene.

Grow and Armstrong⁴ in their recent work on "Fit to Fly" give the following instructions to aviators, which could well serve as a guide to all workers.

No matter how apparently sound, the teeth should be checked at regular six month intervals by a competent dentist. Dental hygiene should be maintained daily.

The various oral occupational lesions considered in this report present a challenge to the authorities in industrial and public health to provide adequate measures for the prevention, early recognition and treatment of oral occupational disease.

SUMMARY AND CONCLUSIONS

1 The problem of oral manifestations of occupational origin must be considered according to the pathologic process, structure affected, etiologic agent and occupational distribution.

2 The oral cavity is a chief port of entry for occupational noxious agents. All medical examinations of industrial workers should therefore include an oral examination.

3 In the study of occupational disease an examination of the oral cavity offers the following advantages:

(a) The oral cavity is easily accessible.

(b) Local effects are readily recorded in exposed enamel and dentin and in the soft structures. The record in the enamel and dentin is often permanent and may reveal past occupational exposures.

(c) Systemic effects may be transmitted in the oral cavity through the blood stream and the saliva and are often manifested in characteristic symptoms.

4 Poor oral hygiene renders the worker more susceptible to oral occupational hazards. These hazards are minimized in the presence of oral health. Oral hygiene is an essential part of industrial hygiene.

5 Adequate provisions for industrial health should include the prevention, the early recognition and the treatment of oral occupational diseases. The problem of reducing oral occupational diseases should, therefore, be met by (a) improving working conditions and (b) establishing and maintaining optimal oral and general health.

6 Further studies of oral occupational disease should be conducted in order to check or confirm previous reports and to discover possible manifestations arising in new industries.

Clinical Notes, Suggestions and New Instruments

MYASTHENIA GRAVIS OCCURRING IN AN INFANT BORN OF A MYASTHENIC MOTHER

FRED I. STRICKROOT, M.D., ROBERT L. SCHAEFFER, M.D.
AND HOWARD L. BERGO, M.D., DETROIT

Up until the time that it was discovered that symptoms of myasthenia gravis were ameliorated by the administration of a parasympatheticomimetic drug the number of cases of this disease reported was small. Although physostigmine definitely benefited patients with this neuromuscular disorder, its side effects were so undesirable that they precluded adequate treatment. Not until 1935 when Dr. Mary Walker¹ of Greenwich, England, first used prostigmine methylsulfate on a myasthenic patient, was there a suitable drug found to treat the condition.

Although the number of such patients who have since been observed is rapidly increasing, owing in part to a suitable diagnostic test,² only a few patients who became pregnant have been carefully observed. Viets, Schwab and Brazier³ have recently reviewed the literature on this subject and state that pregnancy has a favorable effect on the course of the disease, often amounting to a definite remission. In discussing the question of whether or not to abort a pregnant woman who has myasthenia gravis, these authors³ cite the case of a woman who had an abortion performed on the hypothesis that the disease might be transmitted to the child. As far as can be ascertained, there has been no evidence in the literature to lead one to believe that such is ever the case.

However a myasthenic woman has recently been observed through a pregnancy and delivery of a child with seemingly typical symptoms of myasthenia gravis.

REPORT OF CASE

History—M. G., a white girl aged 19 on Feb. 3, 1939 complained chiefly of extreme weakness. Her past history showed that she had experienced an essentially normal childhood and adolescence. At the age of 8 years she sustained a fractured arm which healed normally. When she was 10 or 11 a vague smothering feeling was often noted during hot weather. She had measles, mumps and chickenpox in rather rapid succession at the age of 12, but none were very severe and there were no complications. Growing pains were rather frequently complained of during childhood, although apparently she had normal strength during this period.

Two years before the onset of the present illness her mother considered her thin and somewhat undernourished despite the fact that her weight reached about 120 pounds (54 Kg.) during the summer months. In 1937, when she was 17 and was beginning her senior year in high school she first noted the onset of weakness in the knees when climbing stairs, and finally on several occasions her knees collapsed completely before she reached the top of the stairs, causing her to fall. She did not seem to have the strength to aid herself or even to reach for assistance when she began to fall, and following such an incident she was unable to rise for about ten minutes. Diplopia was usual at the time of falling. Shortly after this group of symptoms appeared the patient began to complain of extreme fatigue especially prominent in the muscle groups of the upper extremities and head. Mastication became a real effort and she had to assist the jaw muscles manually when eating a procedure which took considerable time. After a few minutes of conversation her voice would become nasal and her speech slurred. Writing became almost impossible and a simple procedure such as combing her hair or removing her dress caused extreme muscular exhaustion. Soon she was unable

to turn in bed or rise from a horizontal to a sitting position. She volunteered the information that she believed that her strength was nearly normal for a few seconds after beginning any activity but that extreme fatigue almost invariably occurred before such activity could be carried to completion. A loss of 10 to 12 pounds (4.5 to 5.4 Kg.) during the past year was noted. Muscular pain was not experienced. Two months prior to her first visit she fell, injuring her head so severely that roentgenograms of the skull were deemed advisable. They showed no demonstrable abnormalities. Although dizziness was absent, the patient stated that she had transient deafness usually when listening to the radio, which could generally be relieved by placing her head between her knees for a few minutes.

Both parents were living and in good health. Nothing in the family's past history relevant to the patient's illness was elicited.

A systemic review of the patient revealed nothing of importance except that she always had complained of cold hands and feet. Her grades in school were always passing, although lately they had not been as high as before.

Physical Examination—The patient was thin and undernourished. The skin was dry and pale. The distribution of body hair was typically female. The hair on the head was still normal in amount but not quite as thick as prior to the onset of the present illness. Her weight was 105 pounds (48 Kg.), her height 66 $\frac{1}{10}$ inches (169 cm.), span 68 inches (173 cm.), upper measurement 32 $\frac{7}{10}$ inches (83 cm.) and lower measurement 34 inches (86 cm.). The oral temperature was 98 F., pulse rate 75 a minute and the respiratory rate 18 a minute.

The head was well formed but the cheeks were somewhat hollow and the face had a drawn, drooped expression. The external ears were well formed and close to the head. Both auditory canals were clear of obstructions and both drums appeared normal. The pupils were quite large, regular and equal and reacted normally to light and in accommodation. Ophthalmoscopic examination revealed nothing abnormal and the extraocular movements were normal. The nose was well formed, with no gross obstruction to breathing. The mouth exhibited seemingly normal teeth with slight spacing and crookedness of the upper incisors. The oral mucous membranes showed no abnormality, the tonsils were small and noninflamed and the pharynx was normal. No cervical or general adenopathy was demonstrable. The thyroid gland was neither visibly nor palpably enlarged, and there were no signs of thyrotoxicosis.

The chest was fairly well formed with the breasts well developed and out of proportion to the general configuration of the body. Chest expansion was normal and equal. The percussion note was normal and breath sounds were normal vesicular but somewhat subdued and faint. The heart was not enlarged to percussion, heart sounds were of good quality with no arrhythmia, a faint, soft, sharply circumscribed systolic murmur was heard in the pulmonic area. Blood pressure was 115 systolic and 75 diastolic.

Examination of the abdomen revealed no masses or points of tenderness. The liver, kidneys and spleen were not palpable.

The reflexes were essentially normal throughout except that the biceps and triceps were somewhat hyperactive bilaterally. During the course of the examination the patient's voice became definitely more nasal.

Laboratory Examination—Urinalysis February 9 revealed a yellow and cloudy appearance, specific gravity 1.023, reaction acid, and sugar, albumin and bile negative. The centrifuged sediment contained a few squamous epithelial cells, a small number of pus cells and amorphous urates.

A blood count February 8 showed red blood cells 3,610,000 per cubic millimeter, hemoglobin (Sahli) 75 per cent, leukocytes 6,850 per cubic millimeter, with a differential count of polymorphonuclear neutrophils 54 per cent, small lymphocytes 44 per cent and large mononuclears 2 per cent.

Blood sugar was 87 mg. per hundred cubic centimeters of blood, blood nonprotein nitrogen was 32 mg., blood cholesterol 182 mg. and blood chlorides 471 mg. The Kahn reaction of the blood was negative. The basal metabolic rate was minus 9.4 per cent and on the next day minus 0.8 per cent.

A roentgen examination of the skull showed that the sella turcica measured 9 mm. in the anteroposterior diameter by 8 mm. in the cephalocaudal diameter. The floor and the clinoids were well formed with no erosion. The clinoids were not approximated. Roentgenograms of the long bones for epiphyseal closure showed that all epiphyses of the wrist were completely united, including the distal epiphyses of the radius and ulna. All epiphyses of the knee were completely united. Roentgenograms were made of the chest to determine the condition of the thymus. The chest was sthenic in type, the heart was vertical, there was no sign of a persistent thymus gland and no evidence of pulmonary morbid anatomy.

Course—While the laboratory work was being done in the office, 1 cc. of 1:2,000 prostigmine methylsulfate was injected subcutaneously, due precaution being taken to make the patient think that this was part of the diagnostic procedure and not for treatment. Five minutes later she was asked to attempt to climb the stairs, and after some coaxing she did so without assistance from the railings. Her mother remarked "She hasn't done that in months." Continuous gum chewing for more than a half hour caused no fatigue. At the same time the facies changed remarkably and the drawn expression disappeared. A diagnosis of myasthenia gravis was made and the patient was placed on 1 or 2 ampules of prostigmine methylsulfate 1:2,000 injected daily and 15 mg. of prostigmine bromide by mouth twice a day. During the first week the tablets were increased to 3 or 4 daily, depending on the symptoms, and at the end of the week the injections were discontinued. Oral treatment was then continued at the same dosage and the patient was well maintained for about a year and a half, at which time she began to decrease the dose until 1 or 2 tablets daily would suffice, except for short periods when drooping of the lids, strabismus, diplopia or weakness of the arms made a temporary increase of dosage necessary. In April 1941 she was married, and in September she came for examination in the second month of pregnancy. She was referred to Dr. Burgo for obstetric care. Throughout her pregnancy it became necessary to increase dosage of the prostigmine bromide gradually until 6 or 8 tablets daily was necessary near term. Otherwise pregnancy was uneventful. She was carried through a normal labor and delivery quite uneventfully with prostigmine bromide, taking 4 tablets during the eight hours preceding delivery on April 7, 1942.

The baby (a girl, weight 7 pounds 8 ounces [3,402 Gm.]) was well formed and apparently normal. However, some difficulty was experienced on the third day in getting the baby to take its formula. On the fourth day a decided change was noted. The face became masklike, the facial muscles seemed to lose all tone. On stimulation the baby cried almost noiselessly, with no expression or movement of the facial muscles. The lower jaw remained dropped. The baby could not seem to form the lips for nursing. The small amount of formula which did get into the mouth was regurgitated. Mucus collected in the throat and had to be frequently aspirated. The baby did not sleep but was quite inactive and cried or attempted to cry, frequently, although with little noise and no facial expression. With myasthenia gravis in mind, we injected by gavage a test dose of $\frac{1}{4}$ tablet of prostigmine bromide in an ounce (30 cc.) of formula. The response within half an hour was dramatic. All symptoms disappeared and the baby nursed and took the bottle normally and on stimulation cried with volume and with the normal expression of a crying baby. The effect was maintained by the addition to each four hour formula of a half teaspoon of a mixture containing a 15 mg. tablet to each half ounce (15 cc.) of water. The baby gained well for two days and then prostigmine bromide was discontinued for two feedings. The symptoms returned, although in a milder degree, within eight hours, and prostigmine bromide was again ordered, the first dose to be 1 teaspoon of the mixture described. The baby responded as before and half an hour later took 2 ounces (60 cc.) of its formula. About forty-five minutes later she suddenly turned blue and died, after a Drinker respirator, prostigmine, atropine and adrenal cortex extract had proved useless.

An additional report on the mother was obtained April 29. She had required 4 tablets daily for maintenance until, on April 26, drooping of the lids was experienced before each

tablet was due, with continuous blurred vision. Increasing the dosage to 2 tablets for the next three doses gave relief. Maintenance now consists of 4 or 5 tablets each day.

AUTOPSY REPORT ON THE BABY

Autopsy was performed April 14. A critical external examination did not reveal any evidence of injury or violence. The umbilical cord was still in place and tied with linen cord. It was followed as far as the liver and showed no evidence of abnormality whatever. The body was in firm rigor mortis and showed stasis of blood in its dependent portions.

Gross Examination—The head showed very faint typical forceps markings, otherwise no gross anatomic deviations were noted. A semicircular incision connecting the two mastoid processes was made. The soft parts of the scalp were reflected and the skull cap was removed with the saw, thus exposing the brain. The meninges and the venous sinuses were congested. The spinal fluid in the subarachnoid space had a mild xanthochromic color. The surface of the brain was extremely edematous and very small petechiae were seen in the base of the brain over the medulla and pons.

The thoracic cage showed no gross anatomic changes. Inspection of the thoracic cavity revealed that its organs were of normal size and configuration and were in their normal position. Both lungs were free in their respective pleural sacs and were deep bluish mottled brown. On section the cut surface was smooth, moist, congested and edematous, with diffuse small areas of atelectasis which were more pronounced in the lower lobes. Sections from these areas when immersed in water did not float. The large pulmonary arterioles and veins were filled with blood.

The pericardial sac contained about 2 cc of clear, straw colored fluid. The heart showed no gross anatomic changes. The foramen ovale and the ductus arteriosus were closed. The thymus was found in the anterior mediastinum. It had an approximate weight of 12 Gm. On section the cut surface was of glandular architecture and slightly congested.

Inspection of the abdomen revealed the abdominal organs to be of normal size and shape and in their normal position. The liver was a light brown and on section showed congestion and very mild cloudy swelling. The bile passages, bile ducts and gallbladder were filled with green bile and showed no gross anatomic changes. The pancreas was a grayish pink and on section showed no gross anatomic changes. The spleen had a lilac color. On section its cut surface was semifirm and congested. Both adrenals showed cloudy swelling, with the right adrenal exhibiting a large hemorrhage which involved both medullary and cortical zones. Both kidneys showed classic fetal lobulations. On section they were a grayish brown and showed congestion. The ureters throughout their length showed no gross anatomic changes. The ovaries, tubes and uterus showed no gross anatomic changes.

The diagnosis was (1) edema of the brain with small petechiae over the medulla and pons, (2) patchy atelectasis of the lungs, (3) hemorrhage of the right adrenal and (4) diffuse congestion and cloudy swelling of the remaining organs.

Microscopic Examination—Section of the myocardium showed cloudy swelling and congestion. The brain through the third ventricle showed edema, definite congestion and extravasation of blood outside one of the larger vessels. The kidney showed cloudy swelling and definite passive congestion. The liver showed cloudy swelling and congestion of the central veins. The spleen showed passive congestion. The adrenal showed diffuse blood extravasation in the zone of the medulla. The lungs showed diffuse atelectasis, congestion and bronchiectasis. Many alveoli were filled with serum and red blood cells. Striated muscle showed slight cloudy swelling and capillary congestion. Section through the cerebellum showed congestion of meningeal vessels and slight subarachnoid extravasation of blood. Section of the thymus showed definite congestion with a mild degree of hyperplasia of the thymic corpuscles. There was also mild hyperplasia of the lymphoid parenchyma.

The diagnosis was (1) edema, congestion and petechial hemorrhages of the brain, (2) atelectasis of the lungs, (3) diffuse cloudy swelling and congestion of the remaining organs and (4) mild hypertrophy of the thymus with hyperplasia of the thymic corpuscles.

COMMENT

The diagnostic criteria of myasthenia gravis are generally considered to be on a symptom basis. Microscopic examination of tissue from patients dying with the condition usually shows little if anything of a specific nature. Accordingly, until the introduction of the diagnostic test of Viets and Schwab using prostigmine, the diagnosis was often in doubt. It is generally conceded at the present time that if a patient has characteristic symptoms of myasthenia gravis and responds favorably to the prostigmine test that patient has myasthenia gravis. There is no other neuromuscular disease of similar nature which is known to respond to prostigmine in such a fashion.

According to these criteria, the baby under discussion had this condition, for the requirements of the test were fulfilled. This, to our knowledge, is the first instance to be reported in the literature of myasthenia gravis occurring in a newborn infant. All infants born of myasthenic mothers should be carefully studied in an attempt to find more such cases and thus possibly to aid in furthering our knowledge of this disorder.

MYASTHENIA GRAVIS WITH ACUTE FULMINATING ONSET IN A CHILD FIVE YEARS OLD

A. T. LIEBERMAN, M.D., BALTIMORE

Resident in Otolaryngology, Johns Hopkins Hospital

This case of myasthenia gravis is presented because of several unusual and interesting features associated with it. This disease entity, although uncommon in children, occurs with sufficient frequency for it to be borne in mind when one is confronted with sudden acute dyspnea in children.

REPORT OF CASE

History—J. T. W., a Negro boy aged 5 years was admitted to the Pediatric Service of the Johns Hopkins Hospital shortly after noon of July 6, 1942 with a history of sudden onset of inability to talk clearly or swallow and "rolling of the eyes."

The patient was born by normal spontaneous delivery. He received breast feeding during the first six months followed by bottle feedings with orange juice and cod liver oil daily. His subsequent growth and development was apparently normal in all respects and in general he was a healthy and obedient child. His only known illness prior to the present one was chickenpox at the age of 3 years. His only immunization was smallpox vaccination at the age of 6 months.

Present Illness—The child was perfectly well until the morning of July 6 (the day of admission). After eating breakfast as usual he went out to play. During the course of the morning he came into the house and asked for "soda pop," a bottle of which was kept in the ice box. He drank this without difficulty. Then he spied a piece of chicken, asked for it and got it. He bit a piece but was unable to swallow it. His eyes rotated upward and his mother "thought that he was going to die." She asked him what the matter was, and he responded "Nothing," but his mother noticed that his speech was thick, stuttering and halting. He went outside but did not play. He simply lay on the grass. He was offered food, attempted to eat and retain it but vomited. He seemed quite drowsy and got increasingly worse with "his eyes all off skew," unable to swallow and unable to make intelligible sounds. He could not sleep because of "pam in his eyes." His bowels became quite loose and he passed six watery, non-bloody stools. In the afternoon he was taken to a physician in the neighborhood who referred him to this hospital. There was no preceding history of headache, nausea, vomiting or diplopia.

Physical Examination—The temperature was 37.4 C (99.3 F). The pulse rate was 100. The respiratory rate was 28. The blood pressure was 108 systolic, 80 diastolic.

The patient was well developed but scrawny. He lay motionless on the table, swallowing occasionally with difficulty. One noticed immediately the ocular palsy and bilateral ptosis. The skin was moist, warm and of good turgor. The axillary and inguinal nodes were slightly enlarged. There was nothing

abnormal seen in the head or ears. There was ptosis on both sides, which was transitory, and also a left abducens palsy, which was not constant. The eyes moved irregularly and conjugately, but occasionally one would move erratically. He complained of diplopia. The pupils were large and equal and they reacted sluggishly to light. The consensuals were intact. Ophthalmoscopic examination showed bilateral blurring of the nasal margins of both disks. No elevation of the disks was observed. There was nothing abnormal seen in the nose. The pharynx was slightly injected. The tongue protruded in the midline. The gag reflex was not present. The patient swallowed with great difficulty and choked on trying to swallow water. There was pronounced dysarthria, his speech was almost completely unintelligible. No stiffness of the neck was present. When the body was raised, however, there was pronounced head drop. The trachea was in the midline. The thyroid was not palpably enlarged. The chest was long and narrow. There were no beading, flaring or other deformities present. The breath sounds were unimpaired. No rales were heard. The percussion note was resonant. No pronounced or impaired fremitus was heard. The heart and abdomen were normal. All the reflexes were hyperactive. The Babinski reflex gave a flexor response. The Kernig sign was negative. Decided ptosis of both lids was present as well as inconstant palsy of the left sixth nerve. Considerable involvement of the muscles of the tongue and the muscles of deglutition was noted. One observer felt that there was a definite facial weakness on the left side.

The diagnosis at this stage still remained obscure. Among the possibilities offered were tuberculous meningitis, encephalitis, ruptured congenital cerebral aneurysm and a pontine lesion.

Laboratory Examination.—Lumbar puncture about three hours after admission showed clear spinal fluid under no increased pressure. The Pandy reaction was negative. Two hundred and fifty crenated red blood cells per cubic millimeter were found. No white blood cells or organisms were seen on the smear. Protein was 151 mg. per hundred cubic centimeters. Sugar was 53 mg. per hundred cubic centimeters. No growth aerobically or anaerobically was reported subsequently. Examinations of the blood revealed 11 Gm. of hemoglobin, 4,500,000 red blood cells and 20,126 white blood cells with 86 per cent adult polymorphonuclears, 5 per cent immature polymorphonuclears, 5 per cent lymphocytes, 2 per cent monocytes and 2 per cent eosinophils. The smear showed normocytic slightly hypochromic red cells with no anisocytosis or stippling. A sickle cell preparation showed no sickling. The urine was clear, with a specific gravity of 1.035. There was no albumin or sugar, but the acetone was 3 plus. Considerable amorphous precipitate was present, but no formed elements.

X-ray examination of the skull and sella region appeared normal with no evidence of fracture seen. The heart and aorta were normal in size and shape, the lungs were clear.

Course.—Following the lumbar puncture, the child became much drowsier and was unable to take anything by mouth. He was unable to expectorate his saliva and had difficulty in swallowing it. His neck became slightly stiff, the Kernig sign slightly positive. Ptosis became even more pronounced.

His condition was much the same on the following day and no new developments arose to indicate the underlying disease state. Gavage with 200 cc. of formula feeding was done about 1 p. m. and shortly thereafter, while he was lying flat, the feeding welled up into the nasopharynx and pharynx with choking and extreme respiratory distress. This was immediately suctioned out with relief of symptoms. Subsequently, during the afternoon, he was much distressed by accumulation of mucus in his throat.

About 6 p. m. of his second day in the hospital the patient suddenly jumped up in bed clutching his throat, rolling his head and twitching his shoulders convulsively, throwing himself about the bed and breathing with extreme effort and making crowing sounds. At one time obstruction became complete and he was quite cyanotic. Suctioning was again immediately instituted, a tracheotomy set opened up and I was sent for to perform an emergency tracheotomy. When I arrived about three or four minutes later, the acute laryngeal obstruction had subsided and the child was lying prone in bed with extremely shallow respirations, almost completely abdominal.

The history, symptoms and sequence of events suggested myasthenia gravis, and it was decided to try a test dose of prostigmine before doing a tracheotomy. The effect was most dramatic. Within six minutes after an intramuscular injection of 0.5 mg. of prostigmine methylsulfate, the ptosis had disappeared and his speech had cleared remarkably. Fifteen minutes later the patient sat up in bed, asked for a bottle of soda pop and was alert, awake and able to walk across the floor unaided. There was no longer any doubt about the diagnosis. His next dose of prostigmine methylsulfate, 0.5 mg., was given approximately three hours later, at which time muscular weakness had begun to reappear, again he improved dramatically following the injection of prostigmine. Throughout the night he was given 0.5 mg. of prostigmine methylsulfate intramuscularly every two hours. On the following day prostigmine bromide by mouth was substituted, and since then symptoms have been kept in abeyance by oral administration of prostigmine bromide.

Beginning with a dosage of 30 mg. of prostigmine bromide every three hours, the amount has been gradually reduced through 15 mg. every four hours until now the child is being maintained on a dose of 7.5 mg. every twelve hours.

At the time of this writing approximately eight weeks after admission to the hospital the child is up and about, fully active and alert and except for a slight droop of the lids, has no visible evidence of his disease.

COMMENT

The features of the case of specific interest to the otolaryngologist are sudden acute onset of respiratory distress, to such a degree that an emergency tracheotomy was requested by the attending pediatricians, the sudden illuminating onset of the disease and the age of the patient.

The occurrence of respiratory distress in patients with myasthenia gravis is well known. Approximately four weeks before the admission of this patient I was called in consultation to see a twenty-four hour postoperative thyroidectomy patient in the surgical service with a view to possible bronchoscopy or tracheotomy. The patient with a known preoperative diagnosis of myasthenia gravis had developed severe respiratory distress with laryngeal stridor and cyanosis. When seen, she was in every way a counterpart of the subject of this report. She had been given prostigmine just before being seen, and after a few minutes her respiratory function had so improved that indications for a tracheotomy were no longer present. Again after about six hours she had another episode of respiratory distress, which was again relieved satisfactorily by prostigmine.

In a case reported by Levethan, Fried and Madonick¹ respiratory distress and cyanosis were a prominent feature on the first admission to the hospital; these symptoms were completely relieved by administration of prostigmine methylsulfate but recurred soon after the drug was stopped. Respiratory distress was again a prominent symptom when the patient was admitted for the second time. This was partially relieved by placing the child in a respirator plus administration of the drug, but only for a period of about thirty-six hours. Respiratory failure again set in and, despite large doses of prostigmine the child died.

The mechanism of the production of the respiratory distress was the same in all of the 3 cases cited. In 2 the condition was known to be myasthenia gravis before entrance to the hospital whereas in our case the same signs and symptoms appeared within a few hours after the onset of illness. In our case no diagnosis was made until the trial dose of prostigmine proved the nature of the illness.

The symptoms of myasthenia gravis follow for the most part a rather constant and well defined pattern and are characterized chiefly by the insidious onset of symptoms. In the article by Levethan, Fried and Madonick a review of the salient features in 34 cases of this condition in children is given. In the majority of the cases the onset of symptoms was insidious. No mention is made of any case with a sudden onset in any way comparable to the case described here. "Tatig-

1 Levethan, S. T., Fried, A. J., and Madonick, M. J. Myasthenia Gravis. Report of a Case in Which Prostigmine Methylsulfate Was Used, *Am. J. Dis. Child* 61: 770 (April) 1941.

ability, general muscular weakness and weakness of the ocular muscles comprised the initial complaints in 73 per cent of the cases. Disturbances of speech and of deglutition were found to be late appearing symptoms."¹

I have been unable to find any report in the literature of a case of myasthenia gravis whose onset was as acute as that of the subject presented. Although the patient exhibited almost all the signs and symptoms of a classic case of myasthenia gravis, they were so compressed within such a short period of time (forty eight hours) that diagnosis was obscure and uncertain and proved only when the prostigmine was given. The occurrence of myasthenia gravis, although not common, is of sufficient frequency to be kept in mind. Rothbart² in 1937, reporting on the familial incidence of myasthenia gravis in children, mentioned the onset of symptoms as occurring in early infancy in 2 of his cases. In a review of 87 cases observed by Kennedy and Moersch³ between 1915 and 1932 the age of the youngest patient was 10 years, with the greatest incidence occurring within the third and fourth decades. Viets and Schwab,⁴ in a report of 70 cases of myasthenia gravis observed from 1905 to 1939, similarly report their youngest patient as 10 years of age with the highest incidence occurring in the second and fifth decades. More recently Levethan, Fried and Madonick in a case report reviewed the literature of this disease as related to children. They were able to collect from the literature only 34 cases under the age of 17 years. The average age in their cases was 11.8 years, and only 8 patients were under 10 years of age.

SUMMARY

In a case of myasthenia gravis in a 5 year old child the outstanding features were sudden respiratory distress and the dramatic response to prostigmine, the acute, fulminating onset of the disease and the early age of the patient.

THE TYPHOID CARRIER STATE TREATED WITH SULFAGUANIDINE

MAJOR ROBERT J. HOAGLAND, M.D.
Medical Corps, Army of the United States

There are conflicting reports in the recent medical literature concerning the efficacy of sulfaguanidine in the treatment of the typhoid carrier state. The initial paper by Levi and Willen¹ advocating the use of sulfaguanidine for the treatment of typhoid carriers was followed by two articles, mentioned later, which opposed this form of therapy.

Levi and Willen administered 0.5 Gm of sulfaguanidine per kilogram body weight every eight hours for one week to a biliary and intestinal typhoid carrier who underwent cholecystectomy before the drug was used. Cultures taken of 10 specimens of feces, 3 of them after the use of magnesium sulfate, gave negative results. Specimens were taken between three and thirty-two days after cessation of treatment. The authors stated "This method of therapy is worthy of further trial."

Ten months later, Saphir and his associates² reported the treatment of 5 intestinal carriers with sulfaguanidine in a manner similar to that used by Levi and Willen. They gave the same dose four times a day over a period of two weeks. The blood level of sulfaguanidine did not exceed 12 mg per hundred cubic centimeters. "The results were uniformly unsatisfactory. In all cases in which treatment was given the bacillary excretion continued unabated."²

Cutting and Robson³ treated 6 typhoid carriers with several drugs including sulfaguanidine and reported negative results. One carrier had had a cholecystectomy before treatment. Since examinations of bile for typhoid bacilli were not performed in any case it was not determined whether the persons with gallbladders were intestinal or biliary carriers. Since sulfaguanidine could be effective only in intestinal carriers, these cases hardly constituted a fair test. No patient received more than 12 Gm of the drug daily.

My purpose in this report is, first, to swing the balance back in favor of the use of sulfaguanidine in the cure of intestinal carriers of *Eberthella typhosa* and, second, to present a somewhat different technic of treatment.

REPORT OF CASES

CASE 1—B. M. I., a girl aged 17 years of Japanese descent, was a healthy typhoid carrier to whom was traced a recent epidemic of typhoid occurring in a junior high school.⁴ The patient and her parents stated that she had never had typhoid. Her father, with whom she lived, also was discovered to be a typhoid carrier. Specimens of feces on four consecutive days were found to contain *E. typhosa*. The organism was agglutinated by an antityphoid serum in dilutions of the latter as high as 1:10,240.

She was admitted to the hospital on March 19, 1942 without clinical manifestations of disease. Laboratory investigations in this hospital consisted of blood, feces, urine and biliary cultures. Cultures of one blood specimen and 5 urine specimens failed to reveal the presence of *E. typhosa*. Three specimens of bile obtained by the duodenal tube before the institution of treatment and 3 obtained after cessation of the second course of treatment were free of *E. typhosa*. The flow of bile was variously stimulated by magnesium sulfate, bile salts and olive oil because it was thought that the first named might have an inhibiting effect on the growth of *E. typhosa*. On March 31 sulfaguanidine 2 Gm four times a day was administered, and on April 5 its administration was discontinued. Daily specimens after treatment ceased showed no *E. typhosa* until a specimen obtained on April 12 yielded typhoid bacilli on culture. It was then decided to institute another course of treatment with greater doses of the drug. Therefore 4 Gm of sulfaguanidine was given five times during the day, making a total daily dose of 20 Gm. The drug was given for a period of six days. Two specimens of feces were obtained while the patient was undergoing the second course of treatment. Cultures of both showed no *E. typhosa*. Cultures of feces specimens obtained on fourteen occasions since cessation of the second course of treatment all failed to reveal *E. typhosa*. The last specimen was obtained forty-three days after treatment. Three specimens of the patient's feces were obtained after stimulation of defecation by various cathartics—magnesium sulfate, cascara and aloin were each used once. The blood level of sulfaguanidine during treatment was 2.48 mg per hundred cubic centimeters. At no time during either course of treatment did she have any clinical or laboratory manifestations of undesirable effects of therapy. Urinalyses and blood counts during and after treatment showed normal results.⁵

CASE 2—D. H., a boy aged 14 years of Japanese descent, had been sick at home with mild typhoid which was unrecognized until it was discovered that he had been the source of the only secondary case in the typhoid epidemic referred to in case 1. He had no clinical manifestations of disease. His serum agglutinated *E. typhosa* in a dilution of 1:1280. Two cultures of bile and 6 of urine showed absence of *E. typhosa*. Treatment was instituted exactly as in case 1. Urinalyses and blood counts during and after treatment gave normal results. The patient had five feces examinations before treatment with the presence of *E. typhosa* demonstrated in each specimen. He had seven feces examinations after treatment (the last specimen

⁴ Hoagland, R. J. and Fleming, J. T. Clinical Aspects of an Epidemic of Typhoid Fever. *Hawaii M. J.* 1:307 (May) 1942.

⁵ Since the article was written four additional feces examinations have been done on the stools of patient 1 making a total of seventeen examinations. All examinations yielded negative results. The last examination was performed one hundred and four days after the second course of treatment was discontinued.

was examined seventeen days after treatment) with *E. typhosa* not demonstrable in any specimen.

Since we found⁴ that 60 children ill with typhoid all spontaneously ceased to eliminate *E. typhosa* in their feces, the apparently successful result of treatment of D. H., a convalescent carrier, may have been adventitious. However, the abrupt cessation of constantly positive feces cultures was striking. Moreover, it is noteworthy that the same dosage of sulfaguanidine employed in case 1 produced no clinical or laboratory manifestations of undesirable effects of therapy.

CONCLUSIONS

Two intestinal typhoid carriers—1 a healthy and 1 a convalescent carrier—were treated with sulfaguanidine. It is believed that in case 1 the apparent termination of the chronic healthy carrier state was due to the administration of sulfaguanidine and that in case 2 a similar termination of the convalescent carrier state may have been due to the use of the drug.

Sulfaguanidine should be used in the treatment of the typhoid carrier state in doses as high as 20 Gm a day if smaller doses are ineffectual.

MASSIVE INTRAMEDULLARY INFUSIONS

CAPTAIN ERNEST A. DOUD
Medical Corps, Army of the United States
AND

CAPTAIN JOHN E. TYSELL
Medical Corps, Army of the United States

Occasions arise when there is urgent need for massive replacement therapy and the usual methods for administration are not easily available or practicable. The medullary route as advocated by Tocantins¹ is safe and easily and quickly applied, and a minimum of special equipment is required. Intramedullary infusion should be borne in mind more often by those faced with this problem.

Intramedullary therapy is not new. Tocantins and his co-workers have been largely responsible for developing and popularizing this method. Papper and Roventine² have also advocated this technique for parenteral therapy.

REPORT OF CASE

D. E., a white man aged 32, was admitted to the Station Hospital June 10, 1942 for observation and treatment of a bloody diarrhea. He had a history of recurring attacks since 1936 for which no specific cause or treatment had been found. At the time of admission he was fairly well nourished; there were no signs of acute or chronic loss of blood and the physical examination was essentially negative. The stools were frequent and watery and most of them contained gross blood and mucus. Roentgenograms were typical of an early ulcerative colitis. Proctoscopic examination showed red, friable mucous membrane with multiple small, superficial ulcerations. Many fresh stools were examined for amebae and cysts, not one was found. The flora of the colon was normal. The agglutination tests gave negative results. In spite of all the usual methods of treatment, including a therapeutic test for amebiasis, the disease progressed. The loss of blood continued and on June 22 the first transfusion was given. However, he continued to lose blood, and, between June 28 and July 2, 4,500 cc of whole blood intravenously was required to maintain his red blood cell count between 2 and 3 million. At this time, the general condition of the patient deteriorated rapidly. There was a rise in temperature and pulse rate, the abdomen became

distended and tense, it was impossible to administer food and fluids by mouth. The frequency and volume of the stools increased and he had as many as twenty-five bloody stools in twenty-four hours. The total estimated volume of stools ranged from 1,000 to 3,000 cc a day for ten days and contained a considerable amount of liquid blood and clots.

At this time the patient was in a profound state of toxemia and shock. He was irrational, incontinent and completely incapable of taking food or fluids by mouth and was rapidly becoming exsanguinated. Surgical intervention was considered inadvisable because of the patient's extremely poor physical status. The peripheral veins, which had never been abundant, were completely collapsed or thrombosed. At this point replacement therapy constituted the only means for maintaining life. It was felt that the choice for continuing treatment lay between venoclysis by venesection or intramedullary infusion. Intramedullary infusion was the method of choice because of the need for an absolutely reliable technique for a considerable period of time which an irrational patient could not easily disrupt and which would not require the patient to lie flat on his back for prolonged periods.

On July 3 a sternal puncture needle was inserted into the medullary cavity of the sternum. In the first twenty-four hours 2,000 cc of whole blood and in addition 2,600 cc of fluids were administered through this needle. The needle was left in the sternum from July 3 until July 8 and during this time 5,525 cc of whole blood and 8,600 cc of fluids were administered. Because of the patient's generally improved condition the needle was then removed and it was possible to give 500 cc of blood and 1,500 cc of fluid by venoclysis. On July 9, however, the red blood cell count had dropped to

1,890,000. It was apparent that extensive replacement therapy would still be needed for a considerable length of time. Therefore, in order to obtain maximum ease and certainty of administration and freedom from discomfort to the patient the sternal needle was reinserted. This time it was in place from July 9 until July 12, when the patient's condition again permitted its removal. In this period, 3,500 cc of whole blood and 5,350 cc of fluids were administered.

During the period that the needle was in place (nine days) a total of 9,025 cc of whole citrated blood and 13,950 cc of fluids, a total of 22,975 cc, were administered (shown in the accompanying table). As far as can be determined, this is the largest volume of fluids that has been given to a single patient by intramedullary infusion and the greatest total number of days that a sternal needle has been permitted to remain in place.

Cross section of sternum showing position of needle for intramedullary infusion

The patient was perfectly free to move about in bed without fear of dislodging the needle, and ordinary nursing care was facilitated during these nine days. No discomfort was experienced while fluids were administered by gravity. Rapid injection by means of a syringe while the needle was being irrigated produced a moderate indefinite sense of pressure. At any time it was possible to withdraw blood for typing or chemistry studies, thus eliminating the necessity for additional venipunctures.

By the most careful criteria, no local or systemic ill effects to the patient were observed after large amounts of fluids had been given over a long period of time by sternal infusion. The skin and subcutaneous tissues over the sternum showed no evidence of irritation or infection. The sternum showed no evidence of osteomyelitis or periostitis. Roentgenograms of the sternum taken twenty-five days after removal of the needle were normal.

All infusions were administered by gravity. The rate of flow could be varied at will, and no difference between intramedullary and intravenous rates of absorption was noted.

In a total of thirty-five transfusions of whole blood, a mild reaction occurred on one occasion only.

The patient's condition gradually improved. The red blood cell count climbed from 1,890,000 to 5,020,000. The stools diminished in frequency and gross blood disappeared. The recovery was interrupted by an exacerbation occasioned by an acute infection of the upper respiratory tract two weeks later. The temporary increase in bleeding required three more blood transfusions, which were given by vein. Convalescence was gradual. No further transfusions were required and the patient's condition had sufficiently improved so that on August 11 he could safely be transferred to a general hospital for definitive care.

TECHNIC

The only special equipment is a standard B-D 15 gage $1\frac{1}{16}$ inch long sternal puncture needle with a stylet. It is inserted in the midline after preliminary anesthetization of the skin and periosteum. With the patient flat on his back, the point of the needle is directed toward his head so that the shaft makes an angle of approximately 30 degrees with the skin. The level of choice may be either the lower portion of the manubrium or the upper portion of the gladiolus. We used both sites. It is to be noted that considerable firm, steady pressure is required to penetrate the anterior plate of the sternum. A sensation of "give" is felt as the point enters the bone marrow cavity. If the needle is inserted correctly, the cortex grips the shaft so firmly that the needle stays in place without further attention. A blood-marrow mixture is now aspirated as a test for proper insertion. The infusion is begun in the same manner as is a venoclysis.

The bevel of the needle should be directed anteriorly so that pressure on the needle will not place it flush against the posterior wall of the marrow cavity and interfere with the infusion. If this should occur, it is easily remedied by slight withdrawal of the needle. The site of puncture is given the same care as that of a Steinmann pin. On completion of an infusion, the stylet is inserted and sterile gauze pads are taped over the needle. When needed for further infusion, the stylet is removed and patency of the needle is tested by aspiration. If necessary to facilitate flow, the needle may be irrigated with a syringe of isotonic solution of sodium chloride.

No complications have been reported, but the original proponents warned against certain accidents due to careless or faulty insertions of the needle: osteomyelitis or subcutaneous infection.³ It is difficult to see how accidents could occur if a short needle is used carefully and if it is inserted in the midline.

Tocantins⁴ has justifiably suggested that hypertonic or irritating solutions should not be used and that this method is contraindicated in cases of bacteremia in which a localized suppurative process might be established after the insertion of the sternal needle.

CONCLUSIONS

In a case of uncontrollable hemorrhage from the bowel in ulcerative colitis, a total of 16,825 cc of whole citrated blood and 29,250 cc of fluids was administered by intravenous and intramedullary infusion. A needle was inserted into the sternum and allowed to remain for five days. After an interval of one day it was reinserted and permitted to remain for four additional days. During these periods 9,025 cc of blood and 13,950 cc of fluids were successfully given. This method of infusion was found to be simple and safe and may be considered a method of choice when veins are difficult when a patient should not be permitted to stay on his back for a long time and when a patient is to be transported.

For these reasons we feel that this method should be more widely applied. It is particularly applicable and may prove of inestimable value in the treatment of shock in the field.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE

HOWARD A. CARTER, Secretary

FIVE YEARS OF PROGRESS IN THE FIELD OF AUDIOMETERS AND HEARING AIDS

Report of the Consultants on Audiometers and Hearing Aids

Five years ago the Council on Physical Therapy appointed a group of consultants to assist it in the consideration of hearing aids and audiometers. The art of manufacturing hearing aids and audiometers had steadily progressed and numerous inquiries were coming to the American Medical Association seeking information about them. The Council felt called on to make available this information. Hence it seemed fitting for the Council to appoint a group of informed men to help it gather information on the industrial and professional phases of these instruments.

AUDIOMETERS

One of the first problems before the consultants was the formulation of requirements for acceptance of audiometers and hearing aids. Since there were no universally adopted standards in existence, considerable study was necessary before pronouncements could be published. To assist the consultants the manufacturers of hearing aids and audiometers were asked to attend meetings at which the various problems concerning the physical, electrical and acoustical makeup of the instruments were dis-

⁴ Tocantins, L. M., O'Neill, J. F. and Jones, H. W. Infusions of Blood and Other Fluids Via the Bone Marrow. *J. A. M. A.* 117: 1229 (Oct. 11) 1941. Tocantins and O'Neill.⁵

cussed. One object the consultants had in mind was to study the problem of making available the best possible instruments at minimum cost.

On Feb. 25, 1939 minimum requirements for acceptable audiometers were published. The consultants have had the cooperation of the Subcommittee on Audiometry of the American Standards Association, and the wording of the Council's requirements agree essentially with those of the American Standards Association. The requirements proved to be of immense importance in standardizing audiometers. On the accepted list at the present time are two pure tone audiometers: the Maico D 5 and the Western Electric Audiometer 6-B. Recently the minimum requirements have been revised and now for the first time the electrical power values for threshold of hearing have been standardized and adopted through the valuable assistance of the National Bureau of Standards.

The consultants realized that a method for estimating the percentage loss of hearing should be established. It was pointed out to the consultants that in the courts of law, insurance companies, compensation boards and so on considerable confusion existed because there was no definite or acceptable method of estimating the percentage loss of acuity of hearing. Hence the consultants with the approval of the Council and the House of Delegates of the American Medical Association proceeded to formulate such a method. Several years work terminated in the publication of a method, the "Tentative Standard Procedure for Evaluating the Percentage of Hearing Loss in Medico-legal Cases." This method makes use of a threshold audiogram by which to record hearing loss in decibels and from which percentage loss of hearing may be calculated. A reprint describing the method may be had by writing to the Secretary of the Council. Audiogram charts also are available.

Another problem of interest to the profession and especially the otologists and the consultants is the adoption of a nation wide and acceptable method for testing school children. This problem is now being given careful consideration, and the consultants are particularly interested because audiometers are employed. Differences of opinion exist as to which audiometer is the more efficient, the so called "pure tone" or the phonograph type. Both types have been used and apparently with good results. The Council, advised by the consultants has accepted the Western Electric Phonograph Audiometer 4 C as an instrument for group testing and a "pure tone" audiometer the Maico D 8, for screening purposes. Requirements for acceptance of these instruments have not been formulated. The Council considers them on individual merits in accordance with its Official Rules. Phonograph audiometers will test forty pupils at one time, whereas the pure tone audiometer will test only one pupil at a time. Phonograph audiometers are used in the schools only for screening purposes, while pure tone audiometers are designed and used mainly for diagnosis, but recently they have been advocated for screening test purposes and are being adopted in increasing numbers. The consultants are studying the problem further.

HEARING AIDS

On May 11, 1940 "Tentative Minimum Requirements for Acceptable Electric Hearing Aids" were published. These requirements were general in character, the object being to assure physically reliable and efficacious instruments. The Council has, on its accepted list, twenty three hearing aids. A list of those accepted instruments may be had by writing to the Secretary of the Council.

One of the purposes of the Council on Physical Therapy is to inform the profession and the public relative to the status of apparatus and instruments of a therapeutic or diagnostic nature offered for sale. Instruments and appliances submitted to the Council are considered without charge to the manufacturer and in accordance with the principles laid down in the Council's Official Rules. A product is never "approved" or "recommended" but is "accepted," which means that the Council has found that the instrument meets its rules and requirements, has prepared and published a description, and has included the instrument in its list of accepted devices. When an instrument for instance a hearing aid, is submitted, the Council asks the manufacturer to furnish one stock instrument as it is supplied to the trade, a description of it, evidence to support the claims made for it

in advertising and copies of the current advertising and descriptive literature. The Council does not consider devices unless they are actually on the market. Preliminary samples of the apparatus or experimental models are refused consideration, because the Council is not a developmental or promotional agency. The Council is a judicial body. It reviews investigations and evidence presented by manufacturers of therapeutic equipment and also reviews evidence of investigations which it sponsors. The Council desires physicians and the public to understand that the acceptance of an instrument does not imply a recommendation but means only that the Council has found after due consideration that the proponents of the instrument have conformed to the letter and spirit of the rules.

Exaggerated, misleading and false statements in advertising claims are not permitted in the advertising. The consultants have prepared a list of supplementary rules pertaining to advertising claims for hearing aids which augment the Official Rules. These have been distributed among manufacturers of acceptable instruments. Testimonial advertising is not acceptable to the Council. There are many good reasons for this stand, among which are: (1) Such statements may be purchased, (2) the testifier is seldom if ever informed on problems of the hard of hearing, and (3) the responsibility for statements in testimonials does not rest on the manufacturer and there is no way to fix the responsibility.

A product made in large quantities, e. g., a radio, can be sold at a lower cost per unit than a specialized article, such as a hearing aid, which requires careful workmanship and personalized attention after it is sold. Hearing aids are sold largely by salesmen working on commission. They may or may not have fundamental knowledge of hearing problems or have a great amount of information on the physical principles involved. For the most part they are not trained aside from a small amount of instruction given by the manufacturer or his representative. The more hearing aids they sell, the more money they make. Hence competition is keen and in some instances unethical. Repeatedly physicians and wearers of hearing aids mention high pressure salesmanship in connection with the marketing of hearing aids. Wearers of hearing aids complain about the high price. Much of the cost to the customer is in the salesman's commission. It commissions were omitted, hearing aids costing \$125 to \$150 might sell for \$50 to \$75. One reason for the high cost of hearing aids can be attributed to the aforementioned selling methods. If candidates for hearing aids would purchase them the way spectacles are obtained, hearing aids would be much cheaper.

Manufacturers claim that persons who are hard of hearing resent acquiring an aid, even though having one would make them more efficient in business and give them more pleasure in social intercourse. They say that patients have to be sold so in one sense of the word the salesman becomes a benefactor and promotes good hearing. For the time being, this method seems to be the only satisfactory way of marketing hearing aids. A physician is unethical who recommends a hearing aid to a patient and demands or receives a commission from the manufacturer or agent. It is unfair to the patient, because he is unaware of the transfer of money and if the patient knows it he cannot be sure that the advice to buy a hearing aid was for his own good or simply a scheme for the physician to make extra money in addition to the cost of examination and treatment.

Because of competition among salesmen of hearing aids a patient about to acquire one is literally besieged by salesmen who puff up the values of their own individual instruments. There are claims and counterclaims about superior and inferior qualities of individual aids and about the competitor's product. The patient frequently becomes confused and doesn't know what to believe. This is where the Council and its group of consultants can help the prospective user of an aid by giving reliable information on aids that have been accepted. The Council can influence manufacturers to revise, modify and bring in line with acceptable evidence statements recorded in printed advertising and in descriptive literature. Obviously the Council cannot exercise control over the spoken word of untrained and over-enthusiastic salesmen. The American Society for the Hard of Hearing, its national and local groups, will gladly give advice to the hard of hearing.

At the present time many firms use audiometers (either an acceptable instrument or their own make) to assist them in the fitting of a hearing aid. To an extent, and to a limited extent only, can these instruments help in the fitting of hearing aids. The art of fitting hearing aids has not reached the same perfection as in the fitting of spectacles. Fitting hearing aids is more or less of a "cut and try" procedure, and the audiometer is valuable because it points the way and eliminates much of the guessing and trying. It does not matter whether the audiometer used is standardized or not as long as the salesman knows the characteristics of the instrument.

Employment of an audiometer by a salesman frequently leads to an unpleasant relationship between the otologist and the salesman. A physician's audiogram may record one thing and a salesman's another. There are many reasons why the salesman's audiogram may differ, some of which are: (1) The salesman's instruments are not standardized, (2) the patient may have a cold or some other pathologic conditions not present when the physician made the recordings, (3) the background noise in the room may be much higher, and (4) the salesman may not be qualified. The observational error among experts when making an audiogram may vary as much as 5 decibels from day to day, and insidious comparisons with the physician's audiograms may be made by the salesman.

Glasses have been made and fitted for many years whereas the electrical hearing aid is a little over 40 years old. Five years ago the vacuum tube instrument was hardly known. Hence, comparing the progress made in the two fields one finds that enormous strides have been achieved by the manufacturers of hearing aids. On the other hand greater improvement will have to be made before hearing aids will be as universally worn as spectacles. The physician is aware of this and he knows that many hard of hearing persons soon cast the aids aside because of dissatisfaction of one kind or another. He knows that the patient does not like to be burdened with 12 to 14 ounces of hearing aid equipment that the instrument may be unbearably noisy at times and that extraneous sounds in the aid are annoying.

There is a general dislike on the part of the hard of hearing for wearing a hearing aid. He may think that it marks him as an old man, although it should not because there are many youths wearing them now. When a man loses his vision he is aware of the defect and makes an effort to correct it. With the hard of hearing it is not always so. His family and friends notice his condition much sooner than he does. Deficiency in vision is perfectly obvious to one who can't see distances or can't see to read small print. Deficiency in hearing comes on him gradually, and usually he is able to get along very well to a certain point except when there are distracting background noises. If he has a 30 decibel loss or less in the voice range of both ears he can get along pretty well at near distances missing much, but in general carrying on his business and social activities. A person having a 30 to 40 decibel loss in both ears in the speech range should have a hearing aid for any but near speech. He would be benefited, yet he is the one who is most likely to object to wearing an aid. A salesman finding this person will try to sell him an instrument. When he gets it he may or may not like it. Some days his hearing may be better and other days worse. He may wear it for a while become dissatisfied and then store it in the attic. Battery upkeep costs so much, considering the value obtained from the aid, that he may decide it isn't worth the expense. Hard of hearing persons in the lower income brackets cannot afford to buy batteries. Often the manufacturer of hearing aids blames the physician for not recommending an expense of \$125 to \$175 when he knows there is a fifty-fifty chance that this particular patient will wear the aid only a short time and then discard it. Rather than lose the confidence of his patient, the physician may prefer to recommend lip reading or treatment that will prevent the acuity of hearing becoming any worse or both. A few salesmen and only the ignorant few accuse physicians of non-cooperation, asserting that the physician wants the patient to return and return for treatment because of the fees involved. Ethical physicians will not stoop to such practices. The ethical physician will inform the patient that he can do nothing more to better the hearing that the patient should study lip reading and that a hearing aid will probably help, if the patient will be

content to wear it. Much success has been achieved recently in combining lip reading with the use of a hearing aid. A patient having an average hearing loss of 40 decibels in the speech range in both ears should wear a hearing aid for distances over 3 feet.

Those persons needing a hearing aid are advised to consult a physician who is familiar with instruments that will best help them. A person who uses a hearing device should be advised to safeguard his remaining hearing by keeping in close contact with a qualified otologist.

The manufacturers are to be congratulated on the progress made in this field. They are pulling themselves up by their bootstraps. Research for the most part is financed by the hearing aid companies. Unless they sell hearing aids they cannot improve the instruments. Frequently the model being sold is out of date when compared with the firm's own laboratory model under development. Nearly all manufacturers employ production line methods in one way or another in the manufacturing of the aids.

BATTERIES

Several hundred years ago spectacles were so expensive that only the well to do could afford them. The present day hearing aid falls almost into this category not only because of the initial cost but also because of the upkeep. Batteries cost money. Unbiased persons have reported that battery expense amounts on the average to 3 or 4 dollars a month. Recently the Consultants on Audiometers and Hearing Aids cooperated with the American Standards Association Committee on Dry Cells and Batteries in an effort to standardize the size and terminals of hearing aid batteries. Considerable progress has been made in standardizing A and B batteries for vacuum tube hearing aids, but little was accomplished in standardizing batteries for the older "carbon telephone" type hearing aid. Here there are about as many types of batteries as there are aids. The portable radio has helped in this respect because there is a large demand for radio batteries and in many instances they fit the hearing aid cases and terminals. Special dry cells for hearing aids are so designed that they are more efficient for hearing aid purposes than the flashlight batteries. The flashlight cell is designed for long shelf life, which makes it less efficient for hearing aid purposes. The hearing aid batteries are not designed for a long shelf life but for greater efficiency when used in hearing aids. There are those who have accused the manufacturers of hearing aids and their dealers of carrying on a racket in the battery field by designing batteries that cannot be used in other sets. Manufacturers assert that having special batteries for their sets is a benefit to the industry, since it gives the salesman a source of income to offset his overhead and also enables him to keep in touch with the hearing aid wearer providing better battery and repair service for the hearing aid itself. Be that as it may, wearers of hearing aids still complain about the high cost of batteries. It is the opinion of the consultants that one or two sizes of hearing aid batteries with common terminals that would fit all makes of instruments would lower the battery expense and open the way for the hard of hearing to take greater advantage of the modern hearing aid.

ACKNOWLEDGMENTS

The Council regrets its recent loss by death of two of its most prominent consultants, Drs. C. C. Bunch and W. P. Wherry, who died within twenty-four hours of each other. During their tenure of office they contributed greatly to the success of the consultants and the Council will miss them. It is also fitting to pay honor to a man who first conceived the idea of forming a group of consultants on audiometers and hearing aids to assist the Council in this work, namely Dr. Austin Hayden, who died in July 1940. The Council wishes to express its appreciation to the consultants for their untiring efforts in assisting it with the consideration of these instruments and helping to solve the problems confronting the hard of hearing. They contribute their services gratuitously and devote many hours each month reviewing evidence, scrutinizing claims in large quantities of advertising matter, and investigating and testing instruments. The present membership of the group is as follows: Dr. W. E. Grove, chairman, Drs. George M. Coates, E. P. Fowler, Walter Hughson, Isaac Jones, Dean Lurie, Douglas Macfarlan, C. Stewart Nash, Horace Newhart, Paul Sabine and Burt Shurly.

SATURDAY, DECEMBER 12, 1942

"IMMERSION FOOT"

"Immersion foot" is a term applied to a condition produced by long immersion of the feet in cold water, usually associated with immobility of the limbs and constriction by boots or other clothing. An exactly similar condition was described by Ungley¹ as it affected the ungloved hand of an airman who had lain exposed for twenty-four hours on a snow covered mountain. He believes that the term "immersion foot" is inaccurate as well as inadequate. The ideal term should be applicable to other tissues as well as to the feet and should express both the causative factors, namely cold and the neural and vascular disturbances which result from cold. He uses the term "peripheral vasoneuropathy after chilling." The condition has become an extremely pressing problem because of its frequency among those who have been adrift in boats or rafts after torpedoing at sea.

Ungley bases his conclusion on the study of some 80 cases seen in Scotland in the last two and one-half years. During exposure, which lasted for periods up to fourteen days, the immersed limbs soon became numb, the hands became clumsy and some patients described walking "as if on cotton wool." Pain, tingling and even itching were unusual, cramps sometimes occurred, usually in the calves. Swelling of bare feet was noticed after some hours or days. The skin, red at first, was later pale, "sickly yellow," mottled, blue or black, at sea-freezing temperatures, it might remain vivid red. He describes three stages after rescue. The prehyperemic stage lasts for a few hours to several days. The extremities remain cold, somewhat swollen, discolored and numb, with fairly extensive "glove or sock" anesthesia. Peripheral arteries may be pulseless for some hours and remain so in cases going on to gangrene. A hyperemic stage follows and may last from six to ten weeks. Typical observations in this stage include vascular disturbances of the skin involving temperature differentials, increase in

swelling, especially if the extremities have been warmed, sensory disturbances such as tingling, usually of "glove or sock" distribution, motor disturbances, absence of sweating, and blisters, ulcers and gangrene. The post-hyperemic stage lasts for weeks or months after the hyperemia has subsided. Except for fresh blisters or infections, the extremities are no longer unduly hot in a normal environment. Indeed, for months or years after rescue there may be a cold-sensitive state, giving rise to the Raynaud phenomenon or to coldness which may last for hours after return from a cold to a warm environment.

In a parallel study made recently by three Royal Canadian medical officers,² observations were reported on 142 cases of "immersion foot," almost all of them the result of enemy action in the North Atlantic. The patients had been in life boats or on rafts for periods varying from thirty hours to twenty-two days, the boats almost always containing water to a depth of several inches. At the time of removal of the patients from the open boats or rafts the feet were cold, swollen and waxy white, with scattered cyanotic areas. The patients complained at that time that their feet felt heavy, "woody" and numb, and the feet were anesthetic to pain, touch and temperature. Shortly after the removal of the feet from this traumatizing environment the swelling increased rapidly as the feet became red, hyperemic and hot without sweating, and the pulse in the vessels of the feet was full and bounding. This was followed in about ten days by intense neuritic pains and, in severe cases, by varying degrees of gangrene. Return of sensation and complete motor control may be delayed for many weeks, and pain may recur on exposure to cold and wet.

Ungley maintains that the essential cause of these disturbances is exposure of the limbs to cold insufficient to freeze the tissues. Immersion, he says, has no specific action apart from its effect in keeping the parts cold. Webster and his colleagues,² however, state that the only recorded temperatures of the water showed it to be from 34 to 36 F, and, as the freezing point of sea water is approximately 28.5 F, the feet may very well have been exposed to surface cooling below the freezing point of blood, which is 31 F. Nevertheless, they say, since the condition may occur to those exposed for long periods in subtropical waters, it cannot be classed as a true frostbite. Judging from the patients' history, Ungley says, the following factors influence the occurrence and severity of this condition: time of exposure and temperature of water, footwear (this affords some protection for short exposure, but, because of constriction, is harmful for long exposure, causing swelling of the feet and impairment of circulation), immobility since men who kept moving suffered less than those who sat still, body cooling, as from wind, total immersion, repeated soakings or inadequate cloth-

² Webster D R, Woolhouse F M and Johnston J L. Immersion Foot. *J Bone & Joint Surg* 24: 785 (Oct) 1942.

ing, which reduces the peripheral circulation, seasickness and starvation may be contributory agents, age—men over 40 and youths under 17 died from cold sooner than those of intermediate ages, morale—those who give up hope die more quickly or suffer more severely than their companions when treated after rescue. Colored races are said to be more prone to "trench foot" than northern races, but in this study Arabs fared no worse than Europeans.

The recommendations for prophylaxis and treatment of the two groups are similar. First aid and hospitalization should be directed to avoidance of trauma, slow warming of affected limbs, strict asepsis and adequate supportive treatment. For prophylaxis the investigators suggest that boots and any constricting footwear, if wet, should be removed and oil or heavy grease should be generously applied to the feet while the seaman is exposed. On rescue the patients should be lifted, if possible, and not permitted to walk. Massage should not be attempted. The feet should be exposed and elevated, and the patient given supportive treatment. Dry refrigeration, they say, appears to be successful in reducing tissue loss to a minimum. In the hospitals strict asepsis should be maintained, and the feet should be cooled, if possible, during the hyperemic period.

WAR CASUALTIES AT PEARL HARBOR

The *Hawaiian Medical Journal* in the September-October issue publishes a symposium on the disposition of war casualties of Dec 7, 1941 at Pearl Harbor. The authors and discussers were chosen from among those present and active on December 7, so that only first hand experiences are reported. Lieutenant Colonel Spittler,¹ in his discussion of the treatment of war wounds, stressed two principles, namely thorough debridement and subsequent open treatment. It was his impression that the local use of a sulfonamide powder combined with the oral, intravenous or subcutaneous administration had much to do with the reduction in the incidence of infection in wounds. Gas gangrene was combated by secondary debridement, a sulfonamide locally and generally, and x-ray irradiation. Commander Downes thought that the role of the sulfonamides in securing the amazing results was probably exaggerated. Many other favorable factors existed. The patients were a selected group of healthy young men in excellent condition and exceedingly well nourished. This being Sunday morning, they were clean, rested and not exhausted. In addition, the cases were treated by extremely competent and well trained surgeons. In his own experience 110 casualties were treated at Mobile Hospital No 2. A sulfonamide was used in only 1 case, and in this case infection occurred. It was the only infection that developed in the whole group.

In the treatment of shock, as outlined by Lieutenant Colonel Young,² modern concepts of shock and shock therapy were successfully applied. These consisted of early treatment, even in the absence of clinical signs of shock, by means of transfusions of plasma, crystalloids, isotonic solution of sodium chloride, isotonic solution of three chlorides or Locke's solution intravenously, oxygen as needed, judicious use of sedation and administration of adrenal cortex extract. The highest mortality rate came from abdominal wounds. However, about 50 per cent of these patients for whom operation was possible survived. The improvement in the rate of survival, as compared to the injuries to the gastrointestinal tract in the first world war, was probably due to the liberal employment of the sulfonamides intraperitoneally and orally. Lieutenant Colonel Heaton,³ in discussing the operative procedures in these cases, expressed his preference for open drop ether as the anesthesia of choice for abdominal cases. Adequate blood levels of sulfanilamide during the first twenty-four hours were maintained by absorption of the drug implanted in the peritoneal cavity at the time of operation. Chemotherapy was continued for the next several days by oral or intravenous administration. J E Strode,⁴ in the discussion of chest wounds, emphasized the importance of the first aid treatment of the sucking wounds of the chest. The hole is to be plugged immediately by almost any method at hand. The hemorrhage from the intercostal or internal mammary arteries is controlled by ligation or compression. One must be on the lookout for tension pneumothorax. This is readily relieved by aspiration, with use of a water sealed catheter if necessary. Debridement of the wound is just as essential here as elsewhere. Foreign bodies, blood clots and debris should be sucked out of the pleural cavity and from 8 to 10 Gm of powdered sulfanilamide dusted into the pleural cavity and into the wound itself, after which the chest wall is to be closed tightly, if possible. Dr Cloward⁵ outlined a rather conservative therapy for head injuries. He points out that in many large series of cases it has been demonstrated that only about 5 per cent show increased intracranial pressure, so that any therapeutic measure directed to relieve intracranial pressure, when it is actually not present, will not only not do any good but may even do harm by interfering with the physiologic processes of the injured cells. Morphine or other narcotics should never be given to a patient with a head injury. Increased intracranial pressure is to be treated by lumbar puncture and by 50 per cent dextrose in 100 cc doses given intravenously—this to be done only after trephining over the area of suspected hemorrhage. Orthopedic problems are somewhat dif-

ferent in emergency conditions from those of civil practice because of the frequent necessity of transferring patients to the mainland. This makes the use of cumbersome apparatus undesirable. For these reasons Lieutenant Macpherson⁶ states that traction in his service was discarded in favor of open operation with plating or reduction of the fracture with two or more pins incorporated in the cast. Extensive lacerated wounds of the extremities and compound fractures were placed in plaster casts as soon as possible, since plaster of paris has decided advantages over any other treatment in these cases. The principles advocated by Winnett Orr and tested in the Spanish Civil War were again found to be sound. Sulfanilamide proved of great value in these compound fractures. Lieutenant Colonel Robertson had the opportunity of seeing these patients later in a mainland hospital to which they were evacuated. The general and local condition of the men on arrival was excellent. Prompt and skilful treatment and the use of sulfonamides were credited with the results. Lieutenant Commander Spangler⁷ points out that in burns it is important to treat the patient first for pain, anxiety and beginning shock. In the treatment of lesions, attempt is made to convert a soiled wound into a clean, aseptic wound. The burned area is washed with soap and water, debrided and sprayed with freshly prepared 10 per cent tannic acid solution, followed ten or fifteen minutes later by swabbing with 10 per cent silver nitrate solution. No dressings were applied. The involved area was kept under a warm air cradle with a maximum temperature of 85 F. For hands, feet, face and genitals 1 per cent sulfanilamide and petrolatum was used. Spangler expresses the opinion that this is perhaps the most satisfactory way of handling a large group of burns. Lieutenant Commander Palma⁸ described the syndrome of blast injury of the lungs and of the abdomen. The clinical picture was similar to that described by the British observers. He advises that in all war casualties, regardless of the type of injury produced, if there has been exposure to the detonation of high explosives, the integrity of the chest should be ascertained by x-ray examination, because general anesthesia is contraindicated when there is blast injury of the lungs. Oxygen is life saving and should be administered continuously by tent or the B. L. B. mask. The so-called immersion blast occurs in the water and presents features of shock and of abdominal symptoms.

It is gratifying, indeed, to learn that the Army, the Navy and civilian medical personnel proved equal to the great emergency and delivered a service of the most advanced type. The symposium will undoubtedly exert a definite influence on the further progress of therapy of war casualties.

CRYSTALLIZED POLIOMYELITIS VIRUS

Crystallization of a protein from brains of mice infected with poliomyelitis that has all the infectious properties of poliomyelitis virus has just been reported by Racker¹ of the Department of Physiology, University of Minnesota. Twelve years ago Clark and his co-workers² of the University of Wisconsin reported evidence that the virus of poliomyelitis is found largely in the water soluble globulin fraction of brain cord suspension infected with poliomyelitis. They showed³ that the virus is not precipitated to any appreciable degree by one-third saturation with ammonium sulfate. Half saturation, however, precipitates it almost quantitatively. Somewhat later Howitt,⁴ Clifton⁵ and others found that lipoids can be extracted from infected brain suspensions by means of ether without appreciable decrease in the original infectious titer. After prolonged freezing, Loring and Schwerdt⁶ of Stanford University afterward isolated a noncrystalline macromolecular infectious protein from medulla-cord suspensions infected with poliomyelitis by means of high speed differential centrifugation. The slow autolysis during prolonged storage at -10 C apparently increased the purity of their end product.

Racker's crystallization method is essentially a combination of the techniques of these three previous investigators. Mouse brains infected with poliomyelitis were frozen by Loring's method and picked in solidified carbon dioxide. Some weeks later groups of from 10 to 15 refrigerated brains were thawed and emulsified in 10 volumes of saline solution (pH 7.8). After prolonged centrifugation the resulting clear supernatant fluid was extracted with an equal volume of ether by the Howitt-Clifton technique. The lipid free fluid thus obtained was adjusted to pH 4.0 by the addition of dilute acetic acid and the resulting precipitate discarded. The resultant clear supernatant fluid was first precipitated with 1.6 molar ammonium sulfate and the precipitate discarded. The supernatant fluid was then reprecipitated with 2.3 molar ammonium sulfate at pH 5.6 and the secondary precipitate saved. This precipitate was suspended in isotonic solution of sodium chloride, dialysed for three days in a cellophane tube against isotonic solution of sodium chloride and then brought to pH 4.3 by the addition of tenth normal acetic acid. The undissolved residue was discarded. To the resultant clear supernatant fluid hundredth normal acetic acid was added slowly, drop by drop, until a first precipitate appeared. This precipitate was found under a polarizing microscope to consist largely of crystalline (birefringent) material. X-ray diffraction photographs gave halo effects characteristic of proteins.

A few of these protein crystals were thoroughly washed in thousandth normal acetic acid and then dissolved in dilute sodium hydroxide. On intracerebral inoculation into mice the resulting solution produced typical paralytic symptoms of poliomyelitis after an incubation period of fourteen to seventy-two hours. Racker, however, stresses the fact that this is not proof that the crystalline material represents pure poliomyelitis virus. The possibility that the virus may be merely adsorbed on a protein carrier cannot be eliminated. Recrystallization and higher purification of the infectious protein have not yet been reported.

Racker's cautious attitude is reminiscent of the general interpretation of the earlier alleged crystals of plant viruses. These have been repeatedly recrystallized and are now quite generally believed to be pure virus crystals. So concerned the plant virus becomes an autocatalytic protein increasing in size and depolymerizing at the expense of the infected plant cell. Or the plant virus may be pictured as an ingrafted alien or perverted plant protein multiplied by the plant cell. Racker's results suggest an eventual similar interpretation for the poliomyelitis virus.

Current Comment

LIVER BILE SLEEPS ON

For years "Carter's Little Liver Pills" has been advertised to the public with such claims as the following: "WAKE UP YOUR LIVER BILE—Without Calomel—And You'll Jump Out of Bed in the Morning Rarin' to Go. The liver should pour 2 pints of bile juice into your bowels every day. It takes those good, old Carter's Little Liver Pills to get these 2 pints of bile flowing freely to make you feel 'up and up'." Now Ivy, Roback and Stein¹ report a series of experiments on dogs with the drugs concerned and they conclude that two pills given intravenously or two, four and six pills intraduodenally "exert no cholecystokinetic and choleric effect." The authors continue "That is, they do not cause the gallbladder to contract or stimulate the formation of bile by the liver under conditions which permit the gallbladder and the liver to be stimulated by the hormones which are normally concerned in causing the gallbladder to contract and the liver to secrete." These experiments were carefully conducted, well controlled and meticulously reported, the evidence supporting the authors' conclusions seems to be quite adequate. The active ingredients involved in Carter's Little Liver Pills consist of $\frac{1}{4}$ grain of aloes and $\frac{1}{1000}$ grain of podophyllum per pill. Now that this evidence regarding the lack of the specific value claimed for these ingredients is available, the Food and Drug Administration may concern itself with claims made in or on the package, and the Federal Trade Commission may give due attention to newspaper and magazine advertisements which

either state definitely or imply that these pills have a choleric and cholecystokinetic action. Not many nostrums have been carefully studied by scientists. Many such nostrums require little, if any, study to determine that the claims made for them are false or misleading. The Food and Drug Administration, the Federal Trade Commission and the Post Office Department have accomplished much in the protection of the public against the blandishments of the nostrum promoters. In this case science assumes an active role in such protection by developing scientific data concerning a specific product to refute the promoter's unwarranted claims.

YOLK SAC PROPAGATION OF MAMMALIAN CANCERS

Taylor and his co-workers¹ of the Biochemical Institute, University of Texas, have developed an improved technique for propagating mammalian cancers in the yolk sac of chick embryos. Mammalian carcinomas can be grown on the chorioallantoic membrane of the developing chick.² This technique has proved to be unsatisfactory because of the relatively low percentage of takes and the relatively high egg mortality (65 per cent).³ To obviate these difficulties Taylor injected suspensions of mouse carcinoma tissue by means of a hypodermic needle directly into the yolk sac of four to five day incubated eggs. The mortality rate was practically nil, there were 100 per cent takes by this technique. Twelve to thirteen days later, tumors up to 3.5 Gm in size were obtained after yolk sac inoculation of as little as 0.05 Gm of cancer tissue. The injected material had evidently become attached to the inner wall of the yolk sac, from which it obtained adequate blood supply. In this position there was ample room for massive growth without mechanical interference with the embryo membranes. Tumor masses removed from the yolk wall grew readily when transplanted back into mice. Free cancer cells were apparently diffused throughout the yolk material, since subdermal injections of apparently pure yolk substance from cancer inoculated eggs produced typical tumors in mice. For many problems in cancer research the new method of growing cancer cells in egg yolks should be of value.

MOUNT SINAI, NEW YORK, AND BERNARD SACHS

The ninetieth year of operation of the Mount Sinai Hospital of New York is signalized by a special issue of its journal¹ dedicated to Dr. Bernard Sachs. Both the name of the hospital and that of the physician have long been associated with the best in American medicine. This special issue contains nearly seventy contributions on original and historical subjects. The contributors include the names of many leaders in the profession, who for the most part have been associates or students of Dr. Sachs. Certainly this special issue of the *Journal of Mount Sinai Hospital* is a most appropriate and well merited tribute.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

INTERNS AND RESIDENTS FOR 1943-1944

According to the Procurement and Assignment Service, Washington, D. C., the expansion of the Army and Navy in 1943 and 1944 will demand the services of such large numbers of young physicians that a critical appraisal of all positions held by interns and residents and fellows is necessary.

Interns—Graduates of medical schools who hold commissions in the Army or the Navy will be allowed twelve months' deferment of active duty for the completion of an internship. This makes it necessary that internships begin immediately on graduation. Medical school graduates who are deferred by Selective Service may, under the Selective Service regulations, have their deferments continued through one year of internship. Medical school graduates who on account of sex, physical defects or other causes are not subject to induction or likely to be reclassified by Selective Service are not officially restricted as to the length of internships which they may serve but they too have a responsibility to make themselves available as early as possible for civilian services which contribute to the war effort.

Residents and Fellows—Interns who have already served a year of internship must be considered as residents for the duration of the war. Although the Army and Navy appreciate the importance of graduate training in the various specialties of medical practice, they do not feel that they can at the present time be calling interns to active duty in order that they may continue specialized training in civilian hospitals. Therefore, the only justification for the continuation of residencies and fellowships during the war is that they are essential for the provision of adequate medical care for the hospital patients or for the clinical training of medical students. In view of this situation, there are several principles that must be followed in the selection of residents or clinical fellows for 1943.

First, the minimum number of residencies with which each hospital can function must be determined. For 1942 the Directing Board of the Procurement and

Assignment Service stated that in general this number should be less than 50 per cent of the number of residents that these hospitals had before the war. For 1943 this number must be reduced still more.

Second, having determined the minimum number of residents that are essential, these should be selected from the following groups in order:

1. Physicians who for physical or other reasons cannot qualify for service with the Army or the Navy.

2. Present interns or residents who are deferred by Selective Service. Preference in this group should be given to those who have been deferred in class IV-F and class III-A or III-B and maintain a bona fide family relationship with wife and/or children.

3. Present interns who hold commissions in the Army or Navy. No requests for deferment of individuals in this group should be made until the possibilities of filling minimum essential residencies from individuals in groups 1 and 2 have been exhausted. It is impossible at the present time to give assurance that interns who hold commissions will be deferred. The Surgeon General of the Army and the Surgeon General of the Navy have assured the Procurement and Assignment Service of all possible cooperation in meeting this situation. On the other hand, the urgent needs for medical officers in this age group and the necessity of securing the authorization of the War and Navy departments to hold men with commissions in an inactive status beyond one year of internship make it imperative that hospitals make every possible effort to fill essential residencies and fellowships without depending on interns who hold commissions or those who might be subject to induction by Selective Service.

In case it becomes necessary to request deferment of active duty for any individuals in this group, such requests should be submitted to the state committee of the Procurement and Assignment Service.

Approval of these requests must further be concurred in by the chairman of the Corps Area Committee and the representatives of the hospital and medical education committees.

ARMY

PERCY JONES GENERAL HOSPITAL

As previously announced, the government has purchased the Battle Creek Sanitarium, Battle Creek, Mich., consisting of several buildings, utility facilities, including power plant, water pumping station and electrical generating units, along with 28 acres of ground. Funds have been made available to the extent of about \$1,000,000 for conversion, which probably will be completed by December 15 and the hospital opened for patients about January 1. The hospital will have a capacity of 1,550 beds. Facilities for surgery, genitourinary clinic, central supply room, clinical laboratory and dental clinic were built on the

sixth floor of the old building. The physical therapy department will be on the same floor level in the first floor of the former men's bath building. A chapel is being built on the mezzanine floor of the new fourteen story building and a pipe organ, the gift of Mr. W. K. Kellogg is being installed there.

Nine floors of the fourteen story building are being converted into wards, and the eleventh, twelfth and thirteenth floors are being prepared for housing commissioned and nurse personnel. Contracts have been let for the building of one bachelor officers' barrack, three nurses' barracks and five barracks for enlisted men. Barracks for two hundred enlisted men have been con-

pleted and occupied after remodeling the former nurses' home on the reservation. The staff will consist of some eighty to one hundred officers, one hundred and twenty to one hundred and sixty nurses, physical therapy and occupational therapy aides, dietitians and some six hundred enlisted men. The hospital was named after the late Col Percy L Jones, M C, who entered the service during the Spanish-American War as a captain in the Tennessee Volunteers.

Col Norman T Kirk, M C, is commanding officer, Lieut Col Robert H Kennedy of New York is chief of the surgical service, Lieut Col Walter B Martin of Norfolk, Va, is chief of the medical service and Lieut Col Ingolf B Hauge, D C, U S Army, chief of the dental service. The professional personnel is practically complete and ready to function as soon as the conversion is completed.

EIGHT NEW YORK CITY HOSPITAL UNITS ON ACTIVE DUTY

Eight of the eleven United States Army Hospital units organized in compliance with the Surgeon General's directions and completely staffed by as many different New York hospitals had already been ordered to active duty, according to the New York Times of November 22. The eight hospital units on active duty are:

Army General Hospital No 2 (Presbyterian Hospital Unit)
Army General Hospital No 3 (Mount Sinai Hospital Unit)
Army General Hospital No 9 (New York Hospital Unit)
Army General Hospital No 79 (Long Island Hospital and Medical College Unit)
Army Evacuation Hospital No 2 (St Luke's Hospital Unit)
Army Evacuation Hospital No 7 (Postgraduate Hospital Unit)
Army Evacuation Hospital No 9 (Roosevelt Hospital Unit)
Army Evacuation Hospital No 12 (Lenox Hill Hospital Unit)

Of the eleven hospital units, the remaining three not yet on active duty are Army General Hospital No 1 (Bellevue Hospital Unit), Army General Hospital No 37 (King's County Hospital Unit) and Army Evacuation Hospital No 14 (City Hospital Unit).

This information was made public, according to William S Paley, chairman of the campaign, as evidence of the service rendered to the nation as well as to the community by those who have supported the seventy six voluntary nonprofit hospitals of the city which participate in the United Hospital Fund.

COLORADO HOSPITAL UNIT ACTIVATED

The 29th U S Army General Hospital has been activated as a unit at Fort George G Meade, Maryland, and was expected to be ordered to foreign service in a short time. The medical, dental and administrative officers, nurses, dietitians, physical therapy aide and chaplain were procured and initially trained under the sponsorship of the University of Colorado School of Medicine and Hospitals, Denver. The medical officers received preliminary training at the U S Army Fitzsimmons General Hospital, Denver. The nurses, physical therapy aide, dietitians and surgical workers were activated at Camp Carson, Colorado Springs, and then were to be transferred to Fort Meade as quarters became available. The Surgeon General appointed as commanding officer of the unit Col W C Pollock, M C, U S Army, and assigned nine other administrative officers and five hundred enlisted men to complete the command. The hospital will have a capacity of 1,000 beds, which, if necessary, can be expanded to twice that number. The medical and dental officers and other personnel assigned to this unit as of September 15 are as follows:

Administrative Service

Commanding officer: Col William C Pollock M C
Executive officer: Major Henry J Dillon M C
Adjutant: 1st Lieut Arlice J Moore M A C
Personnel officer: 1st Lieut G Arnold Logan M A C
Receiving and evacuation officer: Capt John D Gillaspie M C
Medical supply officer: Capt John F Latham M A C
Registrar: 1st Lieut Keith D Heuser M C
Commanding officer medical detachment: 1st Lieut Fred Dempsey M A C
Chaplain: 1st Lieut James B Roe Chap C (Prot.) 1st Lieut Francis L Hickey Chap C (Cath.)
Assistant personnel officer: 2nd Lieut Bert W Chappin M A C
Assistant commanding officer medical detachment: 2nd Lieut Maurice P Rees M A C
Two Q M A C supply and utilities and one mess officers are yet to be assigned.

Professional Service

Chief of medical service: Lieut Col Edward G Billings M C
Assistant chief medical service: Major Robert S Liggett M C
Medical service section chiefs: gastroenterology: Capt Frank B McGlone M C
neuropsychiatric: Major Howard P Gilbert M C
general medical: Major Robert T Terry M C
cardiovascular: Major Robert W Gordon M C
communicable diseases: Major Gerald M Trumess M C
Medical service ward officers: Capt Lawrence D Buchanan M C
Capt Joseph D Friedland M C
Capt Paul Haun M C
Capt Leo W Lloyd M C
Capt Paul D Garvin M C
Capt Carl F Arndt M C
1st Lieut Paul M Clark M C
1st Lieut William W Abrams M C
1st Lieut Frank Prince M C
Chief of surgical service: Lieut Col John M Foster Jr M C
Assistant chief surgical service: Major Frederick R Harper M C
Surgical service section chiefs: orthopedic: Major Foster M Matchett M C
urologic: was assigned to Capt Robert M Hall M C (absent as noted)
eye ear nose and throat: Major Ivan W Philpott M C
septic surgery: Major Kenneth C Sawyer M C
general surgery: Major Edgar W Barber M C
Major Jack D Bartholomew M C
Anesthetist: Capt Hermann B Stein M C
Surgical ward officers: Capt James D Morrison M C (ophthalmologist)
Capt James Chessen M C (ear nose and throat)
Capt Charles G Freed (neurosurgeon)
Capt Roy C Rounds M C (orthopedist)
Capt Irvyn E Hendryson (orthopedist absent)
Capt Chauncey A Hager M C
1st Lieut Karl F Sunderland M C
1st Lieut Harold R McKeen Jr M C
1st Lieut James S Haley M C
1st Lieut John C Straub M C
Chief of dental service: Major Arnold H Miller D C
Dental service oral surgeons: Capt Robert M McDowell D C
Capt Andrew P Scott D C
prosthetist: Capt Gordon W Murray D C
Dental service general operators: 1st Lieut Raymond W Weaver D C
1st Lieut Franklin S Garrison D C
1st Lieut Carryl M Becker D C
Chief of laboratory service: Major Rodney H Jones M C
Laboratory service staff: Capt Alexis E Luchencio M C
1st Lieut Alfred S Blauw M C
Chief of x ray service: Major James W McMullen M C
Assistant x ray service: Capt Christopher H Martin M C
Principal chief nurse: 1st Lieut Mary Frances Frieden A N C

Civilian Employees

Dietitians: Miss Doris Odle (head dietitian) Miss Emma J Hollett
Miss Fern A Stone
Physical therapy aide (head): Miss Florence E Bullock
Social service worker: Miss Thera Harder

TECHNICAL MEDICAL TRAINING COURSES

The War Department announced on November 27 that special courses in technical medical training for several thousand enlisted men would begin at nine of the army medical centers, December 1. These men will be schooled in the technical phases of medicine, dentistry, pharmacy, surgery, veterinary medicine, roentgenism and laboratory work and will be chosen at medical replacement training centers and other echelons. The students will be furnished from the nine service commands in the United States, medical replacement training centers, units of the ground forces and air forces. The minimum educational requirements for selection will be high school graduation or its equivalent for laboratory, pharmacy, dental and roentgenologic technicians and common school graduation for medical surgical veterinary and sanitary technicians. Continuing courses are also to be offered. The locations of the schools are as follows:

Army Medical Center Washington D C
Lawson General Hospital Atlanta Ga
Billings General Hospital Fort Benjamin Harrison Indiana
O'Reilly General Hospital Springfield Mo
Fitzsimmons General Hospital Denver
Army and Navy General Hospital Hot Springs National Park Ark
Brooke General Hospital Fort Sam Houston Texas
William Beaumont General Hospital El Paso Texas
Letterman General Hospital Presidio of San Francisco

MORE ADMINISTRATIVE OFFICERS

Graduation exercises were held for the members of another class in the Medical Replacement Training Center's Officer Candidate School, Camp Berkeley, Texas, November 25, all of whom became second lieutenants in the Medical Administrative Corps. The diplomas were presented by Brig Gen Roy C Heflebower, school commandant. The oath of office was administered by Lieut Col Charles L Driscoll, M A C school executive. Col George E Armstrong M C assistant commandant and school director, presided during the ceremonies.

FLIGHT SURGEONS' ASSISTANTS

A class of seventy-four flight surgeons assistants completed the six weeks course in aviation medicine at the School of Aviation Medicine, Randolph Field, Texas, November 21. Col Eugen G Remartz, M C commandant of the school delivered an address. The certificates were presented by Major Emerson M F Weaver, M C.

CIVILIAN DEFENSE

REVISED INSTRUCTIONS FOR FIELD CASUALTY AND AMBULANCE
UNITS OF EMERGENCY MEDICAL SERVICE

The Office of Civilian Defense Washington, D. C., on November 13 issued Circular Medical Series No. 23, which follows:

Because of the diminishing supply of civilian physicians and nurses and the growing necessity to conserve manpower, the following economies in the organization and operation of field units of the Emergency Medical Service are to be recommended to all state and local chiefs of Emergency Medical Service for adoption:

1 *Mobile Medical Teams*—Emergency medical field units are to be composed of mobile medical teams and no longer of squads or groups of teams. Each mobile medical team is to consist as heretofore, of one physician, one nurse and two auxiliaries.

2 *Express Parties*—Immediately on receiving an air raid warden's report of a bombing incident with casualties the control center will dispatch only one express party to each major incident. An express party will consist of one rescue team, one mobile medical team, one ambulance and perhaps one passenger car or station wagon.

3 *Reserves*—Such an express party will usually be sufficient to handle a major incident or a group of neighboring minor incidents with casualties. Additional medical and rescue personnel, ambulances and passenger cars for sitting cases should be held in reserve and should be dispatched by the control center only on subsequent request of the incident physician (head of the mobile medical team) or of the incident officer at the scene.

4 *Reduction in Movement and Use of Medical Personnel*—Mass air raids have occurred chiefly, although not exclusively, at night, both night and day raids are now usually sudden and intense. As protection against a sudden and unexpected attack by the enemy, every hospital having interns or residents is urged to have at least one or more mobile medical teams constantly on call to be ready to respond promptly to the order of the control center. Most alarms are not followed by an enemy attack, the availability of a few mobile teams at each hospital will make it unnecessary in most cities to disturb the depleted and overworked medical profession by requiring them to mobilize at casualty stations throughout the city on every alert. Moreover, the first line mobile medical teams of hospitals also need not be disturbed until medical service is needed at an incident where casualties have been reported. Practicing physicians of the neighborhood should be mobilized to relieve the primary mobile team when there is a continuing need for field services at the incident or when multiple or large incidents make it desirable to activate a casualty station for the care of the slightly injured. Conservation of medical personnel in this manner will, from now on, become increasingly important.

5 *Reduction in Number of Casualty Stations*—Conservation of emergency medical service personnel can also be accomplished by reducing the number of casualty stations which must be equipped and staffed. British experience over three years indicates that most cities do not require more than one casualty station for each twenty-five thousand persons and that they need not be nearer than a mile apart. Casualty stations for the temporary care of minor casualties are required at or near every hospital. They are also required in parts of a city a mile or more from a hospital and in sections which are geographically isolated. Every community is requested to reexamine its casualty stations in the light of these requirements and to eliminate all unnecessary locations.

6 *Economy in the Use of Casualty Stations*—Casualty stations need not be activated in areas where no casualties have been reported. A mobile medical team should always be available at hospitals to activate its casualty station when necessary.

A mobile medical team should be dispatched or assembled at casualty stations near incidents only when casualties have been reported in that vicinity.

The mobile team for a casualty station located at a hospital is therefore best derived from the hospital, a mobile team for emergency service at casualty stations remote from hospitals should be derived either from a hospital, if within 3 miles, or from the physicians, nurses and auxiliaries residing in the neighborhood if more than 3 miles away or otherwise geographically isolated.

7 *Central Control*—The chief of Emergency Medical Service or his deputy at the control center will keep a record of all hospital mobile teams and ambulances in his district and of physicians, nurses and auxiliaries living in the vicinity of each casualty station who are on call for emergency service. He will determine when to dispatch a mobile medical team from a hospital to an incident or to activate community medical personnel for service at an incident or casualty station.

8 *Elimination of Advanced First Aid Posts*—All fixed first aid posts can be eliminated. Experience has shown that under the conditions of darkness, confusion and dirt that exist at air raid incidents it is rarely necessary or even possible to establish a temporary first aid post. In the darkness and dirt it is impossible to do much more for air raid casualties on the spot than cover their wounds, control hemorrhage, apply a simple splint and administer morphine before they are removed to the hospital. Most of this work has already been done by rescue workers and the incident physician by the time the casualty is extricated. Only at a large incident with many casualties may it be desirable to establish a first aid post at an appropriate protected site. Even under these circumstances it should be used as a base of operations for medical personnel rather than a place where severely injured casualties are brought for treatment.

9 *Rescue Units*—Services of stretcher teams are required at hospitals for unloading of ambulances. Stretcher teams (and so called first aid parties) are not required in the field, for whatever first aid is possible at incidents is done by the trained rescue workers under the direction of the incident doctor. To conserve manpower stretcher teams may be disbanded as soon as the rescue teams have been organized and trained or they may be transferred to the rescue service. The equipment of a rescue team will hereafter include four stretchers. An intensive training program for rescue workers will be announced shortly.

10 *Ambulance Units*—To reduce the movement of vehicles during an air raid to economize in driver personnel and to expedite the transport of large numbers of serious casualties from the incidents to hospitals, as many ambulances as possible should be remodeled so as to enable them to carry four stretchers. The use of one and two stretcher vehicles greatly delays the movement of large numbers of casualties to hospitals and may result in needless loss of life. To provide adequate transportation of casualties in mass air raids, exposed cities in the target areas require at least one four stretcher ambulance for every ten thousand persons, depending on the location of hospitals and the distances to be covered, and half that number of passenger cars or station wagons for sitting cases. Specifications for the conversion of used cars into four stretcher ambulances will be provided by the medical division, United States Office of Civilian Defense.

11 *Ambulance Depots*—To be immediately available at all times, four stretcher ambulances and passenger cars (sedans or station wagons) should be parked at hospitals, where drivers are always on duty, or else grouped in ambulance depots located at garages in various parts of the town. Only persons residing in or living in the vicinity of the hospitals or ambulance depots should be assigned as drivers of the vehicles.

12 Interhospital Ambulance Units—An additional number of large vehicles such as busses should be promptly available day and night for the simultaneous evacuation of hospitals during air raid. In heavy air raids it has been necessary to move as many patients from evacuated casualty receiving hospitals to peripheral or emergency base hospitals as from incidents to hospitals within the city. In exposed cities in the target zone it should be possible to evacuate all patients from a hospital in two or at the most three hours without utilizing the ambulance transportation of the field casualty service.

PLASMA PREPARED FOR CIVILIAN DEFENSE USED IN BOSTON DISASTER

Blood plasma stored in Boston by the U S Office of Civilian Defense and the U S Public Health Service in anticipation of enemy action was an important factor in the treatment of victims of the Boston night club disaster, November 28 according to a report to the Medical Division of the Office of Civilian Defense by Dr Dudley A Reekie of Boston, regional medical officer of the first region.

The supply of plasma which the Office of Civilian Defense had available in Boston before the catastrophe totaled 2708 units—sufficient for that number of transfusions. Fifteen hundred units had been acquired jointly by the Office of Civilian Defense and the Public Health Service with permission of the Army, from blood collected for the armed forces by the American Red Cross. Of this amount 500 units of dried plasma was stored in the first regional office, 500 units of frozen plasma in the Boston City Hospital and 500 units of frozen plasma in the Peter Bent Brigham Hospital. Additional reserves amounting to 1,208 units of liquid frozen plasma were on hand in hospital blood banks, the establishment of which had been aided by grants under the program of the Office of Civilian Defense and the Public Health Service. Ninety civilian hospitals in the state of Massachusetts reported during November that they had 3,456 units of plasma on hand. The civilian hospitals in Massachusetts region 5, which includes Boston, had 1,532 units on November 28. In addition to the Office of Civilian Defense reserves, the Red Cross had 200 units in its Boston office. On the request of an official who was unfamiliar with the local resources, the Red

Cross sent by plane from Washington 100 units from Alexandria, Va., 100 units and from New York 72 units. The U S Navy also sent 400 units by plane from Washington.

A total of 1,308 units of plasma is known to have been used in the treatment of victims of the holocaust up to November 30. The greater part, 1,102 units, was used at Boston City Hospital, to which 63 per cent of the casualties were dispatched. Of this amount 627 units was from the Office of Civilian Defense reserve stored at the Boston City and Peter Bent Brigham hospitals. The remainder was supplied by the Red Cross and the Navy. Massachusetts General Hospital, with 20 per cent of the casualties used 130 units from its own plasma bank, which had been aided by an Office of Civilian Defense and U S Public Health Service grant. The remaining 17 per cent of the victims were distributed among Peter Bent Brigham, Beth Israel, Cambridge City, Massachusetts Memorial, Carney, U S Marine, U S Naval, Cambridge St Elizabeth's St Margaret's and Faulkner hospitals. All except the last five hospitals have plasma banks that have received grants through the Office of Civilian Defense and Public Health Service program.

As of Monday November 30 the civilian hospitals of Boston still had on hand 1,000 units of plasma, and the regional Office of Civilian Defense had 873 units. The Red Cross is replacing the Office of Civilian Defense reserve that was used in order that it may again be available for the treatment of civilian war casualties.

Dr Charles Wilmsky, Boston chief of Emergency Medical Service, mobilized ambulances and stretcher teams to transport victims to hospitals. Since immediate hospitalization was imperative, mobile medical teams were not called into action at the scene of the disaster.

Dr Reekie reported that the casualty receiving hospitals mobilized for the emergency according to plans perfected by drills during the past year in preparation for the care of casualties caused by enemy action. 'Staff members took their emergency posts, nurses were ready, information services began at once and Red Cross trained Nurses' Aides reported for duty' his report said. Hospital officials indicated that the casualties received more prompt and organized care than would ever have been possible if the Emergency Medical Service plan for war disasters had not been set up and able to function. Two hospitals easily absorbed the major emergency work of the Boston tragedy, Dr Reekie observed.

MISCELLANEOUS

PUBLIC HEALTH UNDER HITLER

According to *Slovenska Pravda*, Bratislava, of August 25, recently the women's section of the HSLS in Brenner visited the wounded soldiers in the former Jewish hospital of Bratislava. They distributed among the wounded 96 Kg of various fruits, 28 liters of wine, 2,700 cigarettes, 100 cigarette cases and flowers. At first they visited the Croats and then all the others. By this visit the Slovak workers' wives have clearly shown their attitude toward our army.

Zora for August 29 reports that on August 28 a boat with 100 German wounded arrived at Ruschuk.

According to *Aftonbladet* Stockholm, of October 6, new large transports of wounded Germans have arrived in Norway lately. There are now hospitals for wounded Germans in Oslo and ten other places in Norway.

Stefan of October 2 reports that from Sofia 200 wounded German soldiers arrived there that day. They will stay at the convalescent home at Banki at the invitation of the Bulgarian government.

Radio Lyons of October 6 reports that a train repatriating 900 sick prisoners from Germany had reached Soissons on its way to Compiègne. Radio Lyons on the same day reported that some 40 sick prisoners repatriated from Germany arrived in Limoges, where they were greeted by the regional prefect.

According to Radio Lyons of October 8, 452 sick and wounded prisoners from Germany have arrived at the Gare du Nord.

Pesti Hirlap of September 1 reports that more wounded soldiers have arrived at the military hospital at Pecs. They

were taken from the train to the hospital in cars. The train took four days to arrive from Kiev.

Radio Toulouse of September 13 states that a train carrying 233 sick prisoners of war from Germany has arrived in Paris at the Gare de Lyon.

Havas of September 15 states that for over two years seven hundred and fifty doctors have been in captivity. It was necessary to safeguard their rights and their interests. From now on a district will be reserved around the former residence of each doctor now in captivity. No new practice may be set up during the absence of the practitioner or for five years after his return. In towns, doctors returning from captivity will obtain priority for public and private employment. Young doctors still without practices and medical students, will take the place of foreigners forbidden to practice as doctors in France.

The *Social Demokraten* Stockholm, of September 25 states that Norwegian doctors and hospital staffs have won special respect for their anti-Quisling attitude. The quislingites have made repeated and vain attempts to win the staff of the Ullevål hospital. Recently a meeting was arranged at which the Oslo municipal chairman Fritz Jenssen, spoke. Only five of the hospital's staff of fifteen hundred attended.

Het Laatste Nieuws of September 13 announces that, at the beginning of October, Flemish girls will be leaving for the eastern front to serve as nurses with the German Red Cross. All inquiries should be addressed to De Vlag, 42, rue de la loi, Brussels.

ORGANIZATION SECTION

OFFICIAL NOTES

ANNUAL CONFERENCE OF SECRETARIES AND EDITORS OF CONSTITUENT STATE MEDICAL ASSOCIATIONS

HELD AT AMERICAN MEDICAL ASSOCIATION BUILDING CHICAGO, NOV 20 21 1942,
DR HARRISON H. SHOULDERS, NASHVILLE, TENN., PRESIDING

(Continued from page 1145)

Afternoon Session, November 20

THE PROCUREMENT AND ASSIGNMENT SERVICE AND THE AMERICAN MEDICAL ASSOCIATION

JAMES E. PAULLIN, M.D.
President Elect of the American Medical Association
ATLANTA, GA

Since last June it has been my privilege to visit quite a few state associations. The physicians of this country look to the American Medical Association for guidance, for advice for wisdom and for justice in the conduct of the medical affairs of this country of ours. The physicians of this country and, I am satisfied, the general population of this country have implicit confidence in this organization despite the fact that occasionally one will find groups of individuals who will try to leave an impression on the public that such is not the case.

As an association we have many component branches. Practically all the doctors in the Army are members of this organization. Practically all members of the Medical Corps of the Navy are members of this association. Practically all members of the Public Health Service are members of the American Medical Association. The only way we are ever going to get anywhere in solving the problems that now confront us is through an active understanding and cooperation between all of these groups who stand for the best of medical practice that we are capable of giving to the people of this country.

The Procurement and Assignment Service of which I am a member, has before it at present a serious problem which has to do with the dislocation of physicians to meet public needs for medical care in many of these mushroom communities that have sprung up about industrial plants. That problem concerns us, it concerns the state organizations which are a part of the American Medical Association, it concerns the Public Health Service, it concerns industry and it concerns the civilian population.

The Procurement and Assignment Service has laid down a formula which may be useful and which will be useful in solving some of these problems, that is, that most of them must be considered at the state level. The problem that confronts us in Georgia would not be similar to that which confronts Illinois. Basically they are the same, fundamentally they are the same. The technique which can be utilized in each one can follow, up to a certain point, the same procedure. The Procurement and Assignment Service, the American Medical Association through its state and constituent county medical societies, the Public Health Service, industry and labor as represented by the civilian population can sit down and reach some kind of a workable conclusion that will help to solve during the present emergency many of these problems that arise, perhaps not on a basis that would be considered ideal, but undoubtedly on a much better and more logical basis than any haphazard kind of method which can be at the present time instituted.

There are certain states in the United States which now are suffering from a definite voluntary withdrawal of physicians from medical practice. Many of those states are to be found in the part of the country from which I come. It is going to be necessary for a great many industrial plants which are located in these areas to redistribute physicians, to dislocate physicians and to get them to undertake work as a patriotic duty in these various communities. That must be done on a purely voluntary basis.

There are problems that you, as secretaries of your state associations, must take into consideration in helping to carry

out this program. I refer to the licensure of physicians who move temporarily from one state to another and cannot through reciprocity be licensed to practice medicine in that state. I realize that that brings up for discussion in many of these states the problem of states' rights. But at the present time we are in a war and the thing we have to do is to win this war. If it takes the temporary denial of a state's rights to allow a physician who is already practicing medicine in some state and who is an ethical practitioner of medicine and is willing to be dislocated and go to another state to render a patriotic service, I think he should have the right to do it.

Grant these men temporary licenses to practice medicine in a given state under supervision of your board of medical examiners, provided they render service in a community that needs it and needs it badly.

There is set up in each state according to the recommendations of the Procurement and Assignment Service a committee to thresh out these problems. It is a combined committee. It does not represent any group, but it does represent an effort on the part of the Procurement and Assignment Service to obtain the wholehearted cooperation of every one interested in winning this war. That group is set up in a consultative capacity. It consists of the state chairman of the Procurement and Assignment Service, a representative from the state medical association, a representative from the Public Health Service, a representative from industry and a representative from labor. Those are the people who are primarily interested in the medical care of these communities. If this group of people in a consultative capacity—getting rid of prejudices—are willing to go all out to win this war, if they with whatever help may be necessary from federal agencies, provided the state itself cannot finance the program, will see that industry gets help and that these communities are supplied with a reasonable degree of medical care, we shall have accomplished something extremely worth while.

THE HEALTH OF OUR NATION IN WARTIME

SURGEON GENERAL THOMAS PARRAN
U. S. Public Health Service

For the past two years the Public Health Service has been cooperating with the state and local health departments to meet the many health problems arising out of war and mobilization. Some of these are becoming more urgent and more serious. Current information secured regarding health conditions around military cantonments and vital war industries shows that to four hundred and ten such areas 5,700,000 people have migrated. Much of this shift has been to relatively sparsely settled areas.

For a number of reasons well known to this audience doctors, dentists and nurses have not followed the workers and their families into their mushroom activities.

The war activities of the Public Health Service which are of interest to this group have been, chiefly:

1 To aid the states where health personnel has been withdrawn for military service and to supplement personnel in the boom areas. Many health officers had Reserve commissions. Others have gone into the armed services and we have been able in some measure to replace the health personnel, usually with less well trained people, which had been withdrawn. Some urgent situations have been corrected in dealing with elemental sanitation and disease control problems in the boom areas.

2 To strengthen and develop more adequate industrial hygiene services. Many states at the beginning of mobilization had practically no industrial health service. Their work has

been doubled and redoubled, but as yet it has not kept pace with the doubling and redoubling of war industries

3 To aid in the control of venereal diseases, which is a problem accentuated by war. In reference to this sector, I can say there is no evidence as yet of any increase in the syphilis rate in the general population. This result is in contrast to the experience in Great Britain, where during the first year of war there was a 10 per cent increase in the syphilis cases reporting for treatment, in the second year of the war a 20 per cent increase, and in the third year of the war a 40 per cent increase, with the result that although Great Britain started with a much lower syphilis rate than in this country they have lost in the three years of war all the gains they had made in the preceding decade

4 To operate the malaria control program around all mobilization and industrial areas where the disease is prevalent. This is a direct federal operation, with federally employed personnel, from ditch diggers to sanitary engineers and entomologists

5 To provide the medical staff for the Office of Civilian Defense

In carrying out the first three of these objectives and excluding the personnel on duty with the Office of Civilian Defense and malaria control personnel we now have on duty with the state and local health organizations 325 medical officers 282 sanitary engineers, 220 nurses and 490 laboratory technicians and other specialists. This has not met the urgent needs of approximately double those amounts

In reference to our work with the Office of Civilian Defense, I am sure most of you are familiar with the general plan of operation. I shall not go into detail. I should like, however, to clarify the purpose of asking some two hundred hospitals to set up teams to staff emergency base hospitals. The idea in back of this movement is that in the target areas we may have a blitz. If that occurs, there is no time to process appointments, to get people under orders and get them moved. Planning needs to be done in advance. So we have followed the army plan of base hospital organization, except for a smaller staff and have asked some two hundred hospitals, chiefly in the target areas, to organize a balanced team of doctors who will be available in the event of a blitz or other very serious emergency to move into the emergency base hospital which will have been established and start operations

Who is eligible? Any doctor who is at home and who is nominated by the chief of staff of the hospital. Those who are of military age and who wish to join the Army or Navy can submit their resignations from the Public Health Service. The obligation is only for limited service, and that in the event of a dire emergency. Generally speaking, the men who will make up these teams will be the senior doctors, and doctors with physical defects doctors who have been declared essential and who are continuing to serve in that community

From the discussion so far today I think all of us are convinced that the number of doctors in many of the critical war areas is below the danger point. It has been agreed that one doctor to 1,500 population is a minimum safe national average yet there are many communities in which there is only one half or even one fourth of this minimum safe ratio. It is obvious therefore, that it will be necessary as has been reiterated here today, to relocate a considerable number of physicians

I am on record as saying that I do not favor at this time in advance of any general national service act, a special law which would apply to the medical profession. I believe we should try voluntary methods to meet this need. I do not believe that all voluntary methods have been as yet fully explored and exploited

In my opinion, too, this need cannot be met by the Procurement and Assignment Service working alone. I am sure Dr. Lahey agrees to that. In fact one of the principles submitted by Procurement and Assignment Service, and approved by the War Manpower Commission, was as follows: As presently constituted the Procurement and Assignment Service is not in a position to deal with the financial and administrative problems involved in the provision of medical care

This is a job, obviously, which will require very close teamwork between the government agencies concerned—Procurement and Assignment and Public Health Service—the state and local health authorities, and the national, state and local medical organizations, in other words, the medical profession itself. Each has a very essential part to play if we are to be successful

Experience has shown that doctors and dentists are reluctant to move into these boom areas unless there is some definite public recognition of the fact that they are performing a vital

war function. Financial assistance must be provided, at least temporarily, in almost every instance when a physician is relocated. Obstacles to state licensure must be overcome, as Dr. Paulin has just pointed out. Recruitment, selection and assignment of personnel must be carried out under a nationally directed plan. In many of these areas it may be possible to handle the problem on a local or state basis. In many other areas the problem transcends state lines and offers, if not solved, a potential hazard to the success of the war effort

We have already had requests in the Public Health Service from a number of states to supply doctors to go to these areas to practice medicine. They have come with the full endorsement of the health authorities, the medical profession, the local Procurement and Assignment and frequently the State Defense Council as well. We are in the process of meeting a few of these requests in an experimental way, assigning doctors and dentists to communities which have no doctors, or where there are serious shortages. They go as Reserve officers of the Public Health Service, in uniform. They do not collect fees on their own behalf. Their patients usually can pay fees. In one area an arrangement has been made whereby the fees which are collected are put into a fund and used for local public health and medical purposes, hospital bills for the indigent, combined drugs equipping the health center, visiting nurses and so on. The Public Health Service has the legal authority to respond to requests from states for this type of activity, provided the state itself has the legal authority to engage in this activity. In other words, our officer acts as a representative of the state in carrying on a state and local health function

I think most of you are familiar with the present plans of the War Manpower Commission, under which the Procurement and Assignment Service and the Public Health Service are cooperating in an effort to meet these diverse problems. In situations where the Public Health Service is called on to help, it is commonly agreed that state and local authority and resources are incapable of dealing fully with the problem. In such cases there are several approaches. Not all the situations are by any means the same. For example, one or more medical officers might be assigned by the Public Health Service to a locality to render services on a fee basis, the fees going to the local department to help extend the health service. There might be local agreement that these doctors could render services to a specified group of people, for example, to operate an accident clinic, as is being done in one place, or a sick baby clinic, or an antepartum clinic, or to take care of some other group of the population, or where there are a number of doctors already in the community but a shortage still exists, some easing of the situation can be had if a more adequate visiting nurse service should be set up by the health department to assist the doctors on home calls and in caring for the sick at home. Frequently such a nursing service would minimize the need for medical service. They could screen out the needy from the less needy cases. Moreover, from the outside help frequently can be given to doctors already in the community assisting them in establishing a better organized type of service through pooling of the doctors' time and equipment, as an example, by the organization of prepayment medical plans or other types of organization better utilization of the limited medical skill may be made available

All of us know that even before the war our medical forces were not dispersed in proportion to the needs of the population, but proportioned largely on a basis of economic considerations and very unevenly distributed. Their concentration was closely related to per capita wealth rather than to population. In 1940 we had an average of about 98 doctors per hundred thousand people in the United States. This ranged from 49 in Alabama to 157 in New York State, and local variations were even greater. This fact is significant because much of the population shift we have seen as a result of concentration of armed forces and of ship building has been to states and localities previously poorly supplied with physicians. About 42,000 doctors have left civilian life or will have by December of this year to join the armed forces and from published statements it appears likely that a total of 55,000 will be required by the end of next year. This latter figure represents over one third of the active doctors, and more than two thirds of those doctors in the age group from which the bulk of them must come that is, under 45 years of age

In spite of the efforts of the Procurement and Assignment Service, many of these war production areas have lost doctors to the armed forces communities which could not spare any doctors to start with. There is a growing overall shortage which will make it increasingly difficult, I think, to secure the

relocation of doctors in these areas on a nonaided voluntary basis. It is evident, I think, that many of these areas, with only one fourth of the national peacetime average of doctors, with only one third of the depleted national average, are in a situation which gives us all cause for grave concern.

To keep the men in the Army in fighting trim will require ten times the number of doctors per unit of military population as will remain for the civilian population, and yet civilian war workers and their dependents should have good medical care if production is to be maintained at peak efficiency. This is total war. It is just as important to provide health services for the men and women who produce the food, munitions, airplanes and the mechanical equipment for the armed forces as it is to provide adequate health services for the forces themselves. In fact, I think it fair to say that one of the surest ways to reduce casualties is to make sure that the armed forces have more and better equipment than the enemy. If this is done, the health of civilian war workers must be maintained so that they can produce the equipment.

The effects of the current doctor shortage cannot be accurately measured. We have been fortunate, up to now in having, in absence of epidemics, a low rate for respiratory diseases for example, and yet it is obviously important for the worker to have care if absenteeism is to be reduced. Care for his family is important, both from the standpoint of the worker's morale and the very practical reason that an employee with a sick child is likely to take a day off if he has to drive 25 miles to see a doctor.

I think it is instructive for us to compare present demands of physicians, both for the armed forces and for civilians, with those in other nations. Germany has less than 55,000 doctors, a number which is shared by both the armed forces and the civilian population. During the war of 1914-1918 there were about three physicians to 1,000 soldiers in the German army and their number at the present time cannot be very different.

In Great Britain at the outbreak of war there were about 45,000 doctors in the country. The size of the armed forces and the ratio of doctors to enlisted men is not known accurately, but it is believed to be between three and four physicians per thousand men.

The experience of the British in dealing with this problem of doctor shortage has been instructive. By the fall of 1940 it was obvious that the demands of the armed forces for physicians could not be much longer met without resulting in a potentially dangerous situation in the civil population. A temporary committee was appointed to survey the problem. As a result of this committee's studies, recommendations were made in January 1941, and the minister of health issued a memorandum calling on local authorities and voluntary hospitals to review their needs, and indicating that it would be helpful if the armed forces did likewise. Experience soon demonstrated that nothing happened.

At the request of the Central Medical War Committee the government appointed a permanent committee known as the Medical Personnel or Priority Committee to secure the utmost of economy in the use of medical personnel in the armed forces and in the civilian population. The first reports of this committee were published in the *British Medical Journal* of September 5, this year.

After reviewing the needs of the civilian population and the armed forces, the committee, acting with government authority, informed the armed forces it would be necessary for them to use this medical personnel more efficiently. As a result, the Royal Air Force accepted cuts amounting to about 37 per cent of its original demands for the first half of 1941. The army revised its estimates, so that the original demands were reduced nearly 60 per cent, and the navy accepted a cut of 50 per cent in its requirements. The action of this committee with respect to the demands for medical personnel for 1942 has not yet been published. The committee also made several recommendations for the more efficient use of civilian doctors.

That the time has now arrived when similar review must be made in this country I think is evident from the discussions we have had up to now, and the evidence that is before us. I particularly have in mind the address made by the President-Elect of the American Medical Association in Richmond last week, when he indicated that in his opinion it would be necessary to ration doctors, and that it would be necessary for the military authorities to reduce their previously announced needs.

Unless prompt action is taken to solve satisfactorily the problem of medical care for war workers and other civilians in many communities, I fear we are inviting trouble. I am confident that there will be the fullest cooperation of the armed forces in reducing their demands for medical manpower in

order to insure that vital war production will be kept up and to prevent any possible collapse on the civilian front.

In recent weeks we have seen from a demonstration that several branches of our armed forces and those of our allies have the capacity for coordinated action in connection with military operations, and on the civilian front we must develop that same high degree of cooperative action. Mutual trust and confidence is a first essential.

The people of this country have great faith in the patriotism and unselfishness which long has characterized the highest ideals of medicine. Ours is a profession of service to humanity, and indispensable and irreplaceable service in this total war. We are fighting it to preserve our common heritage. Our profession is confronted with the immediate task of insuring a minimum standard of health protection and medical care with our depleted professional forces and to secure that care in a reasonable ratio to the people's needs. In this task we must not fail. Only the wisest use of our resources and the utmost devotion to the common cause will suffice.

THE MEDICAL NEEDS OF THE WAR AND THE SELECTIVE SERVICE SYSTEM

COLONEL LEONARD G. ROWNTREE

Chief Medical Division National Headquarters
Selective Service System

WASHINGTON, D. C.

Selective Service appreciates the privilege of discussing with the secretaries and editors of constituent state medical associations of the American Medical Association the "Medical Needs of the War and the Selective Service System."

General Hershey regrets his inability to be with you this year as he enjoyed meeting with you last year and discussing medical problems of mutual interest. He requested me to assure you of his continued interest and support and also to tell you of his great appreciation for your unrelenting efforts to gear American medicine to the needs of war.

Since your last meeting we have passed from a program of preparedness and national defense to all out, offensive total global war. This situation presents the greatest challenge that our country has faced to date—a challenge to the nation, to every American citizen and especially to every physician.

The nation has a single objective, that of winning the war, but we must cover two functions:

- 1 Create fighting forces capable of victory on land, on sea, and in the air.

- 2 Supply as the arsenal of democracy, the sinews of war—arms, tanks, ships and planes to our own and to the allied forces.

According to the Secretary of War, an army of 7,500,000 is contemplated by the end of 1944, an air force of 2,200,000 ground units of 3,300,000 and a service of supply 2,000,000. According to Secretary Knox, the Navy is already approaching 1,000,000. According to the management Labor Policy Committee of the War Manpower Commission (November 11) it is estimated that the present manpower program will require the services of 62.5 million people (including the armed forces) by the end of 1943. The dual nature of our function introduces unnumerable knotty questions in preferential selection.

Our task as a nation is one of herculean proportions. It calls for individual responsibility on the part of every citizen. From now until victory each and every one of us should live, plan, work, fight and, if necessary, be willing to die for victory.

The war has created an unusual demand for doctors. Medical service is urgently needed on all fronts. The medical profession must and will meet this need but the situation calls for wise and thoughtful guidance and for cool, courageous leadership.

In time of war medicine falls into four categories:

- 1 *Military Medicine*, the care of fighting forces, which takes precedence over all the other needs.

- 2 *Public Health and Industrial Medicine*, prevention of disease and the welfare of the working forces—the men and women essential to production.

- 3 *Research Medicine*, which should be expanded to cover all medical problems important to war.

- 4 *Civilian Practice*, which becomes unduly heavy and arduous and must be attuned to war. With many doctors it involves an eighty-hour seven-day week.

Medical education, as a corollary, becomes of supreme importance, as it is called on to provide more doctors to cover all these four categories. Medical education at the present time is in need of not only a helping hand but also of a protecting arm.

AMERICAN MEDICINE'S CONTRIBUTION TO THE WAR EFFORT

American medicine has more to offer its people than has the profession of any other nation in the world. It is contributing the wholehearted support of a profession, second to none, in quality, numbers and professional attainment. The leadership in the profession is excellent, supplied as it is through the American Medical Association, the Army, the Navy, Public Health, National Research Council and many other medical agencies. Our hospitals, medical schools and institutions are unsurpassed anywhere in the world. They are all being converted to war purposes as rapidly as possible.

Because of increased civilian and military demands, a national shortage of physicians is developing, and this obviously necessitates an equitable apportionment of medical services. This is being effected through the Procurement and Assignment Service, an agency charged with this responsibility by executive order. Its functions are to procure doctors for the fighting forces and to investigate the supply and demands of physicians and to protect the needs of the civil population within each county and state. Procurement and Assignment has aided materially in the procurement of medical men for the fighting forces and has contributed largely to the intelligent distribution of physicians to cover local needs.

The national pool is in the neighborhood of 155,000 doctors with an annual inflow of some 5,300 new fledged physicians. Every effort has been made to increase the incoming stream and to meet the civilian needs despite the large demands of the military establishment. Naturally in war the first responsibility of the medical profession is to the fighting forces. As the shortage increases, the need also increases for organization and reorganization of the services of those doctors who are left on the home front.

Recently, much has appeared in the press concerning the shortage of physicians in rural districts, especially in areas denuded of medical service. The fact remains, however, that many such areas existed previously in times of peace. Yet the present situation does call for some comprehensive program to meet the requirements on a basis satisfactory nationally and to the states and counties concerned.

Importation of physicians may be indicated here and there, but as a rule each state has within itself the wherewithal to meet most of its needs. Where feasible, some simple provision should be given first, and in many instances they may suffice. Such provisions might include (1) visits by itinerant doctors to scheduled clinics, (2) fixed routes and schedules for visiting doctors, (3) part time medical service in designated places, (4) reduction to the minimum of unnecessary demands on the part of neurasthenics and hypochondriacs and (5) provision for emergency needs—medical, surgical and obstetric. These could be met locally through the creation of special telephone exchange and a physicians' bureau, whereby the scheduled physician could be promptly notified of existing emergencies.

Such a program could function successfully only with the agreement of the physicians concerned and through a campaign of education carried on by the state and local medical society. In addition, provision would have to be made with the rationing board for tires and gasoline needed in the transportation of physicians covering these designated areas. Likewise sufficient gasoline would have to be made available for the necessary transportation of the sick. Payment for such medical service could be made a matter of mutual agreement. Not charity but medical attention is desired.

The medical needs of sparsely settled districts and denuded areas should be left in the hands of the medical profession. With the aid of the Public Health Service and assistance from the Procurement and Assignment Service it is capable of meeting this emergency. In order to avoid a crisis in such areas Selective Service and the Army should be kept constantly informed of the local situation by the Procurement and Assignment Service.

The medical profession has met its responsibilities to the Army and the Navy. The size of the Medical Corps of both the Army and the Navy has now met an all time high. The tardiness encountered earlier was due in part to misunderstanding. At present the national quota has been attained and only five states have failed to meet their objective. This has been accomplished to date, without any serious failure on the part of the profession to meet the civilian needs. Recruitment was necessary, though no compulsion or threat of compulsion was necessary on the part of Selective Service. General Hershey stated publicly that he had faith in our profession and was

satisfied that in one way or another American medicine would meet its obligation in this crisis, as it had always done in the past.

Since considerable criticism has been directed unjustly against us it would seem but fair that due publicity be given now to the fact that medicine has met its military obligations to date.

THE EFFECT OF WAR ON THE FUNCTIONS OF
SELECTIVE SERVICE

Selective Service Law and Amendment—The declaration of war led to the amendment of the Selective Training and Service Act of 1940. War greatly augmented the task of Selective Service, increased the scope of its activities and the amount and complexity of its work, and thereby added materially to the medical problems pertaining to the examination and classification of registrants.

Before the declaration of war the age limit of selectees was from 21 to 36 years. Subsequently the age limit of 36 years was reduced to 28 years partially because of the high incidence of defects in older registrants. On Dec 13 and Dec 20 1941, President Roosevelt signed additional Selective Service amendments, some of the major changes in the law as follows:

1. The age limit was increased from 36 to 45 years and provided for the recall into service of those registrants 28 years or over who had been released from service prior to this time.
2. It required every male citizen and every other male person residing in the United States between the ages of 18 and 65 to register.
3. It removed the territorial restrictions as to service of persons inducted into the armed forces.
4. It extended the period of training and service from one year to the duration of the war and until six months thereafter.
5. It made liable for training and service every male citizen and every other male residing in the United States between the ages of 20 and 45. This latter group included aliens both declarant and nondeclarant.

The most recent amendment concerned the 18 and 19 year olds. It provides that:

1. All males between the ages of 18 and 45 years are now liable.
2. That those men of 18 and 19 years who are pursuing a course of study may have induction deferred on request for the completion of the work in the last half of the academic year.
3. That essential workers in agriculture and industry shall be deferred.

Physical Requirements for Induction—The standard for induction at any one time depends on the urgency of need in the creation of an army, the size of the projected army and the size of the manpower pool. In time of peace the standards were necessarily high, but now they have been altered by the War Department to meet the increased and more urgent needs. Defects, minor in nature no longer disqualify. The I-B classification has been eliminated by Selective Service and registrants formerly so classified are now placed either in I-A or IV-F, dependent on their meeting the physical standard established in MR 1-9 (March 15, 1942), an D S S Form 220 (obvious defects).

Change in Type of Physical Examination—Because the final authority for induction rests in the Office of the Surgeon General, and because of the developing shortage of doctors and of the definite increase in the rate of induction, the nature of the physical examinations given by Selective Service and by the army examining boards has undergone substantial change. Selective Service is now giving only a preliminary physical examination, a coarse kind of screening designed to disqualify those with obvious defects. In this connection each local board medical examiner is provided with a list of diseases calling for rejection D S S Form 220.

This type of examination can be done satisfactorily only by a physician and it should not be left to the lay members of the local boards. It consists in careful inspection of each and every selectee in the nude and in action to rule out those manifestly unfit for service. In addition blood is taken for serologic tests and information is assembled locally relating to the personality, nervous and mental record. The data are transmitted to the Army Examining and Induction Board for its guidance. Simultaneously, with the changes in the examination by Selective Service, more and more emphasis has been placed on the quality and thoroughness of the examinations at the army examining and induction center.

At first the necessity for the change to the preliminary type of physical examination was not understood by most of the medical profession but now the wisdom of it is becoming apparent to all. With the growing shortage of physicians and the increasing numbers of men to be processed, the continuation of the complete examination at local board level has been rendered virtually impossible.

Change in Character of Selective Service Examination—Originally, physical examinations were carried out to a large extent in the offices of the examining physicians, but gradually, through the help of the hospitals and medical schools of the country, group team examinations came into existence. They are responsible for reducing the time of individual examinations from forty-five to fifteen minutes.

"Conservation through consolidation" is now being carried to still greater lengths, thanks largely to the excellent leadership afforded us in our work here in Chicago. Selectees are now being examined in groups of 1,000 to 1,200 men, through the services of some thirty to forty physicians and three to five laboratory workers. Whereas formerly 2,000 physicians were necessary for this purpose, it is now being carried on by some 165 doctors through mass examinations held in various parts of Chicago on different days each week.

This new development has met with enthusiastic response and is rapidly spreading to other large urban centers throughout the country. The doctors, accustomed to streamlined laboratory medicine, are now enjoying the experience of recognizing pathologic conditions through the use of their senses and medical experience. This policy of conserving doctors' hours through consolidation of their efforts offers a ready solution of the problem of the shortage of physicians. Though some reports of developing shortage have been made in three or four states, subsequent investigation has revealed that, to date, there exists no actual shortage of physicians for the medical function of Selective Service.

Whereas formerly Selective Service sent up to the army boards all registrants considered likely for induction, the army examining physicians rejected all those who were considered doubtful or questionable for military needs. Now the greater urgency of need has brought the point of view of the examining physician of the Army much nearer to that originally held by the examiners of the Selective Service System.

Need for Reexamination and Reclassification of Rejectees—Beginning September 1, I-B men have been in the process of reclassification. By the first of the year this group reexamination will be almost completed. There now exists a large pool of class IV-F men, and with the increasing urgency of need, many so classified now may be considered qualified, hence some at least of the 1,500,000 men in this IV-F group will undergo reclassification. Undoubtedly, some salvage in manpower will result.

SELECTIVE SERVICE STATISTICS

The third statistical survey by Selective Service jolted the nation out of its complacency so far as its ideas relative to the health and physical fitness were concerned. It constituted a mirror which reflected our defects, deficiencies, disorders and disease. Under the old system of examination 50 per cent of the registrants were rejected, 41 per cent through Selective Service and 9 per cent through the army examining and induction station. With the new system of examination 42 per cent are now being rejected, 113 by Selective Service and 307 by the Army authorities. This reversal of figures is due largely to the fundamental change in character of the two examinations.

Three factors are perhaps responsible for the increase in the percentage of inductions: (1) the lowered standards for admission, (2) the changes relative to age limits and (3) the urgency of need for men in the fighting forces. Doubtless, selection is now based on a somewhat better knowledge of what the Army wants and can utilize to advantage.

Changes Incident to Age—The third survey showed, at the age of 21, 70 per cent qualified for service, whereas at 36 less than 30 per cent were inducted. Now the age limit has been extended in both directions from 18 to 45 years. The information relative to those of 18 and 19 is too limited to permit of conclusions. However, at 22 years 64 per cent qualified, while at 45 only 14 per cent met the requirements. Roughly speaking, at 22 years 13 out of 20 qualified, as opposed to 3 out of 20 at the age of 45. These figures should be given careful consideration in determining age limits for military service, especially in view of the criticism which has already been directed toward the induction of older men, many of whom after induction are failing to meet military requirements.

SELECTIVE SERVICE, THE MEDICAL PROFESSION AND MEDICAL EDUCATION

A cumulative shortage of physicians was foreseen early in the work of Selective Service, and from the very beginning it has been provided for adequately. In February 1941, at the Congress of Medical Education and Licensure, Selective Service presented a positive program covering this field, advocating the

deferment of third and fourth year medical students and first year interns. Recommendations also were made at that time for increased enrolment and for acceleration in the tempo of medical training. Shortly thereafter an Ensign Corps was set up by the Navy and somewhat later a Medical Administrative Corps by the Army in order to assure the armed forces of an adequately trained medical service. In the interim all these suggestions have been adopted and are proving of great value in increasing the output of young doctors.

During the last two years this program has been extended to include, in addition, the first and second year of medical training and the last two years of premedical training. At the present time the premedical student who is a bona fide matriculant in an approved school is considered for deferment. That this program of Selective Service and the armed forces has been entirely adequate is attested by the uninterrupted training of medical men now going on in all of the medical colleges of our country. According to Dr Rappleye the number of graduates in 1943 will have increased from 5,300 to 9,400 and in the following eighteen months to 10,725. This represents an increase above normal of 33 per cent. In addition at least 5,000 refugee physicians are to be considered. It is desirable perhaps at this time to pause and visualize the profession five years hence from the standpoint of war or peace needs and also from the standpoint of the medical students who are now protected up to 1948. Without doubt many parts of the world will have to turn to this country for leadership at that time to meet their postwar medical needs and a large number of physicians can, in all probability, be used to great advantage. A worldwide shortage of physicians will probably constitute one of our postwar problems.

In passing attention should be called to the fact that American medical students studying in Canada are considered by Selective Service exactly on the same basis as students in this country. Some difficulty has arisen from time to time relative to Canadian medical students who are visiting this country for the purpose of study; however, to date these students have been handled on an individual basis and the results have been quite satisfactory.

One Year Internship—In a conference held some eighteen months ago at Selective Service headquarters an agreement was reached concerning a one year rotating internship. Selective Service is still of the same opinion and with the Army and Navy advocates this plan. In Canada, according to Brigadier General Mcakins, nine months internship is in force at present, but the plan calls for a return to the one year internship at the earliest time convenient. Dr Rappleye has officially informed our headquarters that New York is willing and ready to take over the services of all superfluous interns, not otherwise provided for in their fourth intern quarter.

Selective Service has been unwilling to deter medical men for prolonged internships and residencies, since the military need for men of this age is so imperative. Resident staffs can, of course, be created where feasible, with men disqualified for military service with women and with married men especially those past military age. Hardships unquestionably will result, but Selective Service is committed by agreement to this program in the interest of creating an adequate military force.

Protection of Full Time Medical Teachers—Occupational Bulletin 23 issued under date of September 30, was issued by the War Manpower Commission to meet the need for full time teachers of medicine who themselves may or may not be physicians. They may now be listed as essential men and will be considered as such by Selective Service, if properly certified.

Substandard Schools—Recognizing the fact that substandard schools, if denied protection will disintegrate, Selective Service has sought advice in relation to two schools in particular. Students of these schools are now being deferred and the graduates of these schools are being commissioned at the discretion of the Surgeon General under conditions imposed by his office. Two of these schools in the opinion of Selective Service, are sufficiently well qualified to entitle them to thoughtful consideration. It is hoped that official action concerning them will be forthcoming at an early date.

SOVIET SUGGESTIONS OFFERED BY SELECTIVE SERVICE TO MEDICAL EDUCATORS

Because of its many broad national contacts Selective Service feels impelled to offer some suggestions to medical educators of the country—some of which may appear to merit your consideration.

1 Pooling of Students, Faculties, Faculties in Large Urban Centers—With the large increase in the educational burden which has fallen on medical teachers, the pooling of medical

students, facilities and faculties might effectively be accomplished in certain of the large urban centers. The advantages of such a program under existing conditions are fast becoming apparent. To us it seems that this warrants careful study.

2 *A National Board for the Selection of Medical Students*—With the induction of the 18 and 19 year old men, medical education will be forced to undergo certain modification. Irrespective of the auspices under which such education is conducted, safeguarding of the "selection" of medical students should be exercised. Only those specially trained in this field are capable of making the wisest selection, and wise selection is of national importance now and also for the future. In this connection, Selective Service has suggested the creation of a supervising national board of admission to medicine which would be comparable in some respects to the National Board of Licensure. Such a board would permit the pooling of the premedical students and their wisest selection and distribution among medical colleges. Applicants could be selected up to 50 and 100 per cent in excess of the needs and continuous screening be exercised, thereby reducing the number to the optimum who can be accommodated and to those best qualified for training and graduation.

3 *Wartime Changes in Teaching*—Changes in the curriculum to meet war needs are desirable. Obviously, many changes are needed in the present day to meet the medical needs of the fighting forces. In this connection Selective Service respectfully requests that some consideration be given to the problems of the selection of men for military service. The curriculum should give prominence also to personality problems and to nervous and mental states of men scheduled for military service. Dental defects, since numerically they early constituted the greatest cause of rejections, should be given the attention they merit.

PROBLEMS CREATED BY THE INDUCTION OF YOUTHS OF 18-19 YEARS OF AGE

The induction of the 18 and 19 year old youths creates many new problems especially in relation to college students. Our interest naturally centers most on premedical students. There are two methods of handling the situation, or possibly a combination of the two.

1 Occupational deferment to a selected group of students, which would permit them to continue their education through a period of college preparation agreed on by the Army, the Navy and other governmental agencies on the one hand, and the educational institutions on the other.

2 The creation by the Army and Navy of one or more special enlisted corps reserves.

Dr Willard C Rappleye in a recent letter has submitted some very interesting information. The American Council on Education has appointed a Committee on the Relationships of Higher Education and the Federal Government to consider and propose the most effective manner in which these policies could be implemented. That committee, of which President Edmund E. Day of Cornell University is chairman, has recommended to the Army and Navy that collegiate training corps be created at designated institutions for the Army, Navy, Marines and Coast Guard. If the general plan is carried out, these corps will be made up of young men who have been inducted through Selective Service into the armed forces and who have then been selected during the period of their basic military training of approximately thirteen weeks to enter college for a period of professional or specialized training and education.

It has been proposed that the selection of candidates for these several corps and their retention for further training shall be made by the appropriate military authorities in cooperation with the educational institutions. The boys will be under military discipline, in uniform and on government subsistence and pay. Since the boys for the Collegiate Training Corps will be selected because of their ability and aptitude and without regard to their ability to pay for a higher education, many promising students will be given educational opportunities which otherwise would not be available to them.

"It is planned that as far as possible the inducted young men may apply to any university, college or junior college which will require such candidates to undergo specialized and general officer training of a standard approved by the military authorities. There is likelihood that the students in the Collegiate Training Corps will be obliged to pursue a year around curricula not to exceed four semesters.

"The medical school authorities believe that it is not possible to select medical students until after a certain period in college. It would be necessary, therefore, to earmark likely candidates in numbers considerably larger than can be accommodated in

medical schools and screen this number from time to time until it is brought down to the proper proportion."

Because of the kaleidoscopic changes which confront us, General Hershey is unwilling to offer any plan of action at the present time. He asked me, however, to state that the present Selective Service policies in this field will hold subject to change, of course, in the event of any radical change of policy on the part of the War Manpower Commission.

No doubt it is obvious to most of you that since the average age on graduation from high school is 17 1/2 years, adequate numbers of premedical students will be available for one year of premedical training at least, and that without any new form of protection. In addition, the new amendment to the Selective Service Act provides for deferment for those in the second half of any academic year of training provided they request it.

The crucial question from your point of view is, I know, Will protection materialize in some form? At least it is being attempted. Dr Edward C Elliott, Chief, Professional and Technical Personnel of the War Manpower Commission, informed me that medical students will be high on the list of priorities. He states that I might quote him as saying "Highest pre-ferment is being requested for premedical students and we expect to get it."

Before leaving this question, attention should be called to the recent action of the Council on Medical Education and Hospitals of the American Medical Association whereby uniform standards for admission are recommended and also a uniform period of study two years of premedical work and three years of accelerated training in the medical colleges.

REHABILITATION AND PREHABILITATION

The medical care of soldiers is the best that the country can give. More medical attention, however, is needed for rendering registrants well and fit prior to induction and also when possible after rejection.

As you all know, in October of last year President Roosevelt presented his plan for the rehabilitation of 200,000 men rejected by Selective Service because of physical defects. This program was subjected to a pilot test of a limited scope in the states of Maryland and Virginia. However, the change in the physical requirements for induction and the decision of the War Department to induct I-B men resulted in the wholesale induction of those registrants originally scheduled for rehabilitation. After a four months trial General Hershey decided that the results did not justify the effort on the part of Selective Service. The problem was, therefore, referred to the War Manpower Commission for allocation to some other agency better equipped to carry on the program. This to date has not been done.

The need for a national program for rehabilitation is still great and it should in all probability include not only rejectees but also sick essential workers in war industries. Those vitally interested in this field will find in the service of the New Jersey Rehabilitation Commission a model which might well serve the national need.

The program of prehabilitation was suggested by Selective Service some one and one half years ago. It is now sweeping the nation in the various preinduction programs that are being developed. It embraces two features:

1 The correction of remediable disqualifying defects prior to examination.

2 A program of physical exercise designed to harden and toughen the fiber of youth.

Many preinduction educational programs involving physical training are now in operation in various localities throughout the country. One such program has been developed in New York State under the leadership of Governor Lehman's war council and the professional direction of Dr Hiram Jones. This has attained unusual success. More than 3,000,000 students in New York State are now undergoing physical training of the most desirable kind. This program also constitutes a model worthy of consideration for national needs.

Education, Health and Physical Fitness—The responsibility for the physical condition of the youth of this country does not rest on them alone. The situation represents a combined failure on the part of the state, the community, the parents, the teachers and the individual. The correction of the existing situation calls for the combined effort of all those listed.

On the campus the "student health organizations" occupy an unusually fine position, not only to determine physical defects, but also to remedy them. The student health organizations are creating "wartime health councils" to meet the needs of approximately one-half million university students.

For all the various physical fitness programs suggested, wise medical guidance is highly desirable, indeed quite necessary. In this connection, Selective Service has suggested the creation of an official council on student health in the National Headquarters of the American Medical Association, analogous to the Council on Industrial Health. Such a council, no doubt, could help very materially in determining the reasons for past failure and also in developing adequate programs for betterment of health and physical fitness among American students.

THE PROBLEMS OF NERVOUS, MENTAL, PSYCHOSOMATIC, VENEREAL AND DENTAL DISEASES

Selective Service is attempting to improve the efficiency of selection for military service, especially in the field of nervous and mental disabilities. It is attempting to assemble and transmit to the army boards as much recorded information as is available on the nervous and mental state of the registrants. The Army is attempting to increase its efficiency in this field through the work of psychiatrists and psychologists and through a three day period of observation when needed. In addition, rejectees who are considered as unjustly disqualified are subject to study by psychiatrists on the medical advisory boards. In the event of disagreement with the Army's decision, such registrants can be and are resubmitted.

Psychosomatic diseases are being made the basis of intensive investigation through the cooperation of the National Research Council, special studies are being initiated on groups of men rejected because of cardiovascular disorders. The possibilities in this field are thereby being explored through a pilot test now being conducted.

The wisdom of the United States Public Health Service in demanding serologic tests is now apparent to all. The Army is developing a program for venereal disease through the induction of a limited number of cases of uncomplicated gonorrhea. No doubt the program will expand as facilities for the medical care of venereal diseases are provided.

In this connection, attention might be called to the experimental approach to treatment now being conducted in Wesley Hospital under the direction of Dr. Bundesen, president of the Chicago Board of Health. It represents a serious attempt to compel treatment, to render cases rapidly noninfectious to determine the effectiveness of different procedures, and the amount of treatment necessary under the different regimens. This is an experiment that merits careful scrutiny on the part of the Army, the Navy, Selective Service and other agencies.

The situation in the dental field in this country as revealed by Selective Service is far from satisfactory. Despite the excellent work of the dental profession, the simplest rules of dental hygiene are being largely neglected. As a result there is need for dental rehabilitation, and above all for a more comprehensive program for the prevention of dental disease, and for the wholesale extraction of teeth.

In closing, Selective Service wishes to express its appreciation for the cordial cooperation of the American Medical Association, the Association of American Medical Colleges, the American Dental Association, the National Research Council, the Army and Navy of the United States, United States Public Health Service, Veterans Administration, the Procurement and Assignment Service and other federal agencies. All of these agencies have contributed much directly to the war effort, but in addition they have helped indirectly also through their hearty cooperation in all the medical functions of Selective Service.

PHYSICIANS FOR CIVILIANS

CRIUGHTON BARKER, M.D.

Secretary of the Connecticut State Medical Society

NEW HAVEN, CONN.

It is almost my wish that, instead of speaking to you, you might talk to me, for I would like to know what you think about the shortage of doctors and what the circumstances are in your localities. Some of you come from states where I have never been, and although the purposes and ideals of medical care are fundamentally the same everywhere I know there are important little differences of tempo and practice that must be considered whenever we think of medical care in a given area, and you have that on the spot information.

You and I are the quiet stewards of the professional affairs of more than a hundred thousand physicians giving a basic human service across this great land, and the knowledge of medical practice that we have gathered from our experiences, from our successes and our failures, is not equaled by any other group of people. To be sure, we are secretaries and kind of

bookkeepers for our societies, but we do lots more than collect dues and arrange banquets and try to find medical prima donnas who are not dreary after dinner speakers. That is what it may seem that we do, but there is constantly flowing across our desks a stream of knowledge and information about medical practice and medical care and medical people within our areas that cannot be duplicated, and we more than any others are responsible for what the public thinks about medicine in our home states. In a small state like my own all of this is relatively simple but I know that others or you have this knowledge too in great states like New York and in great empires like Texas. Much of the knowledge that we have might not stand sharp critical analysis by professional planners, for it is knowledge that cannot be filed anywhere except in our heads and hearts, and to us a doctor is bound to be more than a card with a lot of holes punched in it and a community is more than a pin on a map. The possession of knowledge has always brought responsibility and our understanding of the present medical care problems brings us a grave interest in their solution.

Many things have happened since you and I met together here last year. Probably no one of us then imagined how rapid the sequence of events would be and certainly no one of us now would dare to guess how far reaching will be their effects.

First we were concerned in seeing that the armed forces had their doctors, and although an official government agency was established for this purpose and in only a few instances were state secretaries personally involved with the activities of that agency the knowledge and machinery that we have was put immediately to work to aid in the accomplishment of the job then at hand. For the present, at least it is done. It was done in different ways in different places for some of us are fire eaters and like to swing our arms around, and others are calmer and more deliberate, but it seems that just about as much was accomplished one way as the other. You and I can see some mistakes that were made and often we know why they were made and that the making of those mistakes contributes to our present dilemma. We know that the careful and well ordered process that had been wisely set up by the Procurement and Assignment Service was in some instances set aside by the occasionally precipitate methods of the army recruiting boards. We know that fine as the Procurement and Assignment Service was in its concept and valuable as it was, it was limited in its usefulness by lack of authority and that it could do a better job if it might be given some implements besides thought and persuasion. We know that the public was not always accurately informed about our progress and that there were occasions when the patriotism of physicians in this country was unhappily assailed. More than anything else we know that the whole job has been done by harassed and busy men without thought of reward, and for them we have nothing but respect and admiration.

Now as the glow of our first achievement wanes we find ourselves faced with the necessity of sitting down and looking over what is left and deciding what to do next. No one questions anywhere that the men in the services must have the very best of medical care. American people take that for granted just as they take for granted that we are going to have the best guns and planes and generals and it is no part of ours to enter into the debate if the ratio of physicians to the troops, as prescribed by the Army and Navy is too great. That is a matter to be decided by expert knowledge and experience which we do not have. Be that as it may the public now quite rightly wants to know who is going to take care of it when it gets sick. There are a lot of people at home with important jobs to do, and this phase of medical care in wartime belongs peculiarly to us. I may be wrong in this observation, but it is my opinion that the public looks to the Army and Navy, that is to say the government for the care of our soldiers and sailors but that same public still has respect and hope for American medicine and looks to us to see that it is taken care of on the home front. I have discussed this subject in lots of places during the past few weeks on trains with strangers with people whom I know, all kinds of people and I have not yet been impressed that many of them think that it is a government job. Perhaps I have gathered an incorrect impression and even though it is right it may not work but I am sure that you and I, with the knowledge that we have and the confidence that is given us, have a great responsibility in seeing through this part of the wartime medical program. I know the same government agency that was entrusted with the selection and the recruiting of officer candidates has been given the responsibility in the civilian field also but we have a job to

do alongside that agency, helping it at every opportunity, because we know the circumstances of medical care and medical practice within our states better than any one else and through the means at our disposal we can add to and improve that knowledge from every nook and corner of this country.

The most valuable knowledge we shall acquire is to know whether there is actually a shortage of physicians in a particular area. There has been some hysteria about this in spots. Sometimes important and vocative people think there is a shortage because their own doctor or doctors have gone away and we should not be surprised that persons in public life or aspiring to position in public life, have grasped on this exciting subject of doctor shortage as a means of obtaining attention for themselves. By this I do not mean to imply that there are not some areas in need of doctors but nice judgment has to be brought to bear on the problem in every case and all the facts viewed against the background of local conditions, and I think we are capable of doing it.

Our methods for answering the problem and helping with the relocation of physicians can be simple and free of all the time consuming detail of officialdom which is surely something these days. Within every state there are always some doctors seeking new places to locate and looking for fields that are greener, and we are quite likely to know about these men. I realize that now there are not a large number who come into that class because many of them are already in the services or they are busy enough where they are but we shall be able to pick up a few, and perhaps in some states it will take only a few to fill the dangerous gaps that have been left. In most states the state society is closely related to the medical examining board where licenses to practice medicine are obtained, and although it is uncertain how many applicants for new licenses there will be in the immediate future at least we do have an opportunity to know about those that are issued and can study the possibilities of locating some of the new licensees, and in other instances understand and make clear the possibility of licensing physicians who can be removed from another state.

Some of the problems that present themselves may be answered by a redistribution of medical time. That is to say it is possible, and has already been done in some places, to have the physicians remaining in a community spend a part of their time, perhaps a morning a week, in a nearby area whose population has expanded and where medical personnel is inadequate. No agency can adjust a delicate matter like this as satisfactorily as a medical society. Probably the local society could do it best because its members understand the level of fees charged in that locality and could, without favor, arrange a distribution of the work among men willing to do it. State societies may well take the leadership in proposing arrangements of this kind leaving the final details of operation to the county association. More efficient use of the time of doctors can be accomplished if the public gives just a little help and is willing to be considerate about sending calls to the doctor's office early and not expecting much care for trivial things. Our part in this is to see that the public is informed and frankly ask its help, public opinion will not put doctors into critical areas but it will help in the effort to adjust.

In some cases I know that none of our measures will be successful and other means, perhaps drastic means, will have to be discovered, but the first large part of the answer I believe, is up to us. Maybe it is too early to be optimistic about the extent of the assistance that we may give, but it is also too early to be pessimistic, and let us not have it said that we did not try and that we did not see that it was something our people expected us to do and we did the very best we could about it. Above all, let us seek the truth and know what the circumstances are. This will require flexible and unselfish thinking on our part. Then when we know that truth let us tell our people honestly and fairly, confident that they will understand and try to save them from being misled and alarmed by propaganda from any source.

In making the suggestion that a large part of this responsibility belongs to you and me as secretaries of state medical societies, I do not wish to seem to trespass in any way on the function of the Procurement and Assignment Service and whatever we do must always be done in cooperation with that service and in the spirit of being helpful to it. In most states this cooperation will be easy for I know that all of you have worked closely with the Procurement and Assignment Service in the past. Right now this is medicine's greatest enterprise as I see it, to see that our hard working people who are winning the war at home are taken care of, that their productivity is not interrupted and that their health is safeguarded. It is our job now just as it always has been.

CHAIRMAN SHOULDERS The Chair will take occasion to state that the Committee on Medical Preparedness of the American Medical Association was created in 1940. It was created at the request of government authorities. At the end of one year that committee recommended that a procurement and assignment agency be created. However, it was recognized then that the doctor left at home and not wearing a uniform would still be participating in the war activity. A committee was created, and Dr. Walter Donaldson was made chairman.

FUNCTIONS OF WAR PARTICIPATION COMMITTEE

WALTER F. DONALDSON, M.D.

Secretary of the Medical Society of the State of Pennsylvania
PITTSBURGH

Up to the present, there has been no specific request made of our committee beyond one which concerned itself with the problem that has been extensively discussed here today and that has to do with medical service more especially to the war related industries.

The War Participation Committee of the American Medical Association, in response to the request which came from the Manpower Commission through a subcommittee of Procurement and Assignment, headed by Dr. Selby, asked the Council on Industrial Health to develop a plan which would enable the medical profession to contribute more directly to industrial health activity in small industrial plants. That action came as a result of the direct challenge made by Mr. McNutt at the Atlantic City session of the American Medical Association last June, at which he said, having given full credit to the American Medical Association's Council on Industrial Health and Dr. Selby's Committee on Industrial Hygiene Health and Medicine for having arranged many problems that there yet remained the need to reach and obtain the cooperation of local practitioners and that the efforts up until that time (in June) had not produced results.

If they have not produced results, it is not the fault of the Council on Industrial Health here at the home office. We learned that rather belatedly in Pennsylvania. If any one of you has as yet failed to call them to your help and aid, I recommend them to you highly. They not only came into Pennsylvania and helped us organize certain counties, they not only came there and were represented at county society medical meetings but they sent a splendid exhibit to our annual session and I again recommend them to all of you.

I know I shall not need to bestir the memories of many of you very much to ask you to remember the effect of the challenge contained in the statement that went forth four or five years ago all over this country to the effect that one third of the people in the country could not obtain medical service when they needed it. It stimulated most of us. I am sure, into improving the opportunities for more people to get more and better medical service in most of our states and I shall be very much disappointed if every one of our state medical organizations doesn't accept this challenge by Mr. McNutt to proceed to improve the opportunities for your own members to learn something at least about the new problems that are developing under modern war industries. It is foolish for us to claim we already know it because there are new risks developing with every new process in chemistry or in industry.

However it is not beyond the reach of the average state and many of the county medical societies to bring their members up to date on the basic principles of these problems. What we need I believe, is to hold our present position in the respect of the people of this country in relation to this important problem and there is no more important problem than the winning of the war. We are all satisfied of that. And when the people of this country hear, as they always hear the unfavorable things such as "There are not sufficient doctors in this country who know anything about industrial hygiene to serve the all important war industrial work"—when such a challenge becomes broadcast, then you should immediately react in such a way as to let the people know that we are on the way to meeting that situation. They are fully aware of the fact that this is not only a changing world but a changed world and they don't expect a profession like ours which depends largely on basic sciences to keep six months ahead of events but they do want to know that we, who accept the responsibility for representing the rank and file of the medical profession are alert and are doing everything we can to see to it that our members learn to meet this situation.

And I would feel that I wasn't meeting this, my first opportunity to speak to you as a chairman of a very important committee whose responsibilities I almost shirked from, if I didn't

try to lay on your shoulders the responsibility of going back to your home states with the determination that no county medical society under your jurisdiction will go another thirty or sixty days without once again having this responsibility brought home to it

Our committee wants to recommend that every state medical society develop as rapidly as possible a Committee on War Participation, whose functions may yet need to be determined, but whose principal function to begin with, at the present time, is to see to it that these things that mean so much to the future of the practice of medicine are kept under observation

There isn't a state medical society, and there shouldn't be a county medical society that isn't ready to say "Yes, we are here, not to take complete leadership, but to endeavor to coordinate all the agencies in our district that should be connected with this health project" That is your responsibility, that is your function. Don't attempt to create the impression that you want the entire leadership, but assume the initiative and then carry the ball so that you may at least have a coordinating influence that will result in every group in every community turning to the county medical society and the state medical society because they know there are men there and committees there who don't claim to know it all, but who do want to help bring about the necessary results to win the war in as short a time as possible

GENERAL DISCUSSION

DR MICHAEL A TIGHE, Boston Dr Lahey has told you that one of the serious difficulties which his agency is meeting is the matter of the failure of states to recognize that we are in a war and that something ought to be done about loosening up some of the licensure regulations in these states. We have met that situation in Massachusetts. We discussed this matter with our board of registration and medicine and found that it was sympathetic to the proposition. It took the matter to the governor of the commonwealth, and he said "If the Massachusetts Medical Society approves of it I will under my executive wartime powers, issue such an order" The attorney general, in considering it, asked us to demonstrate that there was in Massachusetts at that particular time a necessity. We could not demonstrate it in Massachusetts at that particular time, but the attorney general distinctly said, and I have a copy of the letter which he sent to the secretary of registration and medicine in my hand, "When and if such a time arises, when and if it becomes necessary for the proper performance for the proper medical care of the people in Massachusetts, I will give my assent to such a regulation" I move that this group of editors of medical journals and secretaries of state societies be recorded as favoring such modification of state licensure laws for the duration of the emergency as will facilitate the voluntary movement of physicians from one state to another for purposes of practicing their profession, when such movements are recommended by the Procurement and Assignment Agency

SECRETARY OLIN WEST I don't want to discuss the motion myself other than to state that I have recently heard in personal conversations with members of the Association who drop in to see us from time to time from various states that they feel this matter ought to be considered not alone from the standpoint of dislocation but also from the standpoint of relocation after the war is over

DR GEORGE H KRESS, San Francisco In California I think we would be somewhat dubious concerning the value of the proposed expression of the assembly. Where are these doctors to come from whom we are going to send to other states, and why should it be necessary to break down the licensure laws which in some of the commonwealths have taken years and years to bring into being? Only last week I was speaking with the secretary of the state board of medical examiners on this very subject, and he hoped that any contemplated measures having to do with a change of the licensing standards of the state of California would be given most careful consideration, because our experience out in the Far West has been that by and large it does not work for the development of better standards. It seems to me that a method of this kind had better be left to the individual states and the constituent state associations to work out for themselves

DR A T MCCORMACK, Louisville, Ky I don't think there is any danger of anybody going to any of the states who haven't sent their quota to the Army because there are enough of them staying in California, and in these other states there will be no necessity for anybody going there. We expect somebody to come from California to Kentucky if the situation

remains as it is. If the situation remains the other way around we shall be delighted to receive them. I will say that anybody who comes to Kentucky—we need about two hundred—will be licensed in fifteen minutes if he is recommended by his county medical society as an ethical member of the practice and legally qualified to practice. We are hospitable. We shall be happy to have them and will see that they get a good living in medicine and are given real opportunity for fine service. We are having lots of extra babies down there, and we ought to have somebody to take care of them. I think you ought to amend your resolution to say that we wouldn't expect any of the states who haven't given their quota to the armed forces to offer any hospitality to those who come from without

DR W P EAGLETON, Newark, N J As one who has had a good deal of experience in the building of the medical licenses in the state of New Jersey, who has seen all the stages which they have gone through—you know we are far ahead of any other state, we license osteopaths and we give them the right to practice medicine and surgery, provided they will fulfil certain requirements—and you fellows won't recognize them. You needn't laugh. You are doing the same thing that you did to the homeopaths. We began in 1890 and, one after another, we have added to the original medical practice act. I think it is a great mistake for somebody from Massachusetts, who has a school they want to recognize and don't know how to recognize it, to come here and offer a resolution with which we all agree, but when you establish a rule without knowing what you are doing—it is a mistake to adopt any resolution that in any way would put the separate states on more or less the defensive if they didn't want to concede to it. I think this matter should be referred to the Council on Medical Education and Hospitals and then they can call in whom they please

DR HAROLD S DUFFIN, Minneapolis As one who has had the privilege of serving as a member of the directing board of the Procurement and Assignment Service I would like most enthusiastically to endorse the expression of appreciation voiced by Dr Lahey for the splendid work that has been done by the corps area and state committees of the Procurement and Assignment Service. The men on these committees are the ones who have done the job and who have made the Procurement and Assignment Service function and work. You really are the ones who are on the firing line and I use that term advisedly. You have done an excellent job. Knowing this it makes one's blood boil to read statements in the lay press by self-styled experts on medical care either in special articles or in hearings before Congressional committees that imply or state directly that the Procurement and Assignment Service program has failed miserably and that some other agency should be given the authority to draft and assign physicians to meet civilian needs on a national basis. I have had the privilege of visiting many state and corps area offices of the Procurement and Assignment Service and nothing could possibly be more heartening than to see the excellent job that has been done by the men on these committees, and it has been done under difficult situations with little support, assistance or even direction from a central office. I am sure there is no other agency or no other group in this country that could possibly have done half so good a job. As I say, those of us on the directing board realize that it is really the men and the secretaries of state societies who live, in a sense, behind the forgotten men in this picture because they have done much of the actual work for the state and local committees

As to this problem of medical care, particularly projecting the needs of the armed forces into 1943, as Dr Lahey and other speakers said this morning, the needs of the armed forces will increase during 1943 and in the conference Dr Lahey spoke of a tentative figure as to the number of physicians that safely can be withdrawn from civil practice for 1943 as being agreed on by the heads of the various armed services, the Public Health Service, the War Manpower Commission and the Procurement and Assignment Service. Steps at the present time are in progress to assign to the states a reasonable quota of this total need to be provided. These quotas will be arrived at in essentially the same manner as the quotas of last year. They will be distributed, however, over several months of the year that is, I think you will receive monthly quotas rather than an annual quota. In withdrawing additional physicians to meet these 1943 quotas, in spite of the fact that they will be much smaller than the ones for 1942, we are faced with a much more difficult job than we have at the present time, because there are relatively few areas from which doctors can still be taken without causing severe problems in relation to provision of adequate care for the civilian population. The state committees

of the Procurement and Assignment Service will soon receive from the central office a request to reclassify every physician remaining in each of the status. Every physician should now be reclassified as to whether his services are essential for civilian medical care or whether his services can be made available either to the armed forces or for medical service to meet emergency civilian needs in other areas. The Procurement and Assignment Service is anxious that the most careful possible consideration be given to building up these lists of physicians who can be made available, and we are anxious to have not only lists of men who can be made available but the order in which they should be withdrawn from the civilian population. You will receive those requests in the near future.

As to this problem of provision of medical care for the civilian population, the importance of that, I am sure, was appreciated by most of us months ago. It fell to my lot for the Procurement and Assignment Service in Washington to do a good bit of the leg work that led up to the development of certain principles and policies of procedure and I had the privilege and the Procurement and Assignment Board had the privilege of consulting with the U. S. Public Health Service, which is concerned and has a responsibility in this field, with the officials and Trustees of the American Medical Association, and with other groups, and I want to say that from every source we received nothing but assurances of complete and wholehearted cooperation. It seems to me, and to all of us, that there never has been a greater expression of willingness and desire on the part of these groups to work together to meet this common need. As I think many of you know, out of a great many preliminary discussions there was formulated a set of principles to govern the provision of medical care in these emergency areas. Those principles were agreed to by the Public Health Service and by the Trustees of the American Medical Association and were then submitted and approved by the War Manpower Commission. Following the acceptance of the principles, the next step, obviously, was how to make them work, how to put them into practice. Dr. Barker has presented the working possibilities that have been considered. One of the fundamental points in those principles that we all were anxious to see adopted was that, as far as possible, these problems of medical care should be met by local medical facilities, particularly at the state level. As to how to meet these problems, the suggestion has been made by the Procurement and Assignment Service that a committee be formulated in the state to investigate the need. Obviously the first question is to determine just what the need is. Reports that we are now getting indicate that in many areas there is really no emergency problem in medical care. In other areas the problem is not one of providing additional physicians but the problem is one of meeting public health needs. Possibly there is a sanitation problem, or there may be public health nurses or some hospital facilities that are needed rather than physicians. In other areas there is need for physicians. When those needs exist or are determined to exist, the next step is how to meet them. There again such a committee, representing the interests of the various groups that are concerned with this problem, should undertake to formulate and put into operation a plan for meeting that need.

I am sure that all of us concerned with the Procurement and Assignment Service were particularly pleased at Dr. Fitzgibbon's report this morning on how this situation is being met in Oregon, because that was a report of a practical situation being met in exactly the manner we hope most of these problems will be met. There will be situations, of course, in which it is impossible to meet the medical needs in the manner that Dr. Fitzgibbon and his group have done it in Oregon, but even in those situations where additional physicians are needed and it may be necessary to bring them in from other areas within the state or possibly attempt to get physicians from other states, we feel that the state committee should formulate the plan that seems best adapted to the particular situation. In formulating those plans, the Procurement and Assignment Service on the corps area level and on the federal level, and the Public Health Service on the district and federal level in cooperation with the Procurement and Assignment Service is more than glad to offer consultation service and to assist in every way in appraising the need and in helping to work out what seems to be the best possible solution. It has been suggested that some of these can be met by better utilization of the physicians already in the area. In other instances it will be possible to induce some physician to move into the area just on a private practice basis. Another possibility that has suggested itself, and seems practical in some situations, would be

to put the physician on a salary or on part salary for a period of time. That would be particularly true if you are going to get young physicians who don't have the funds to set themselves up in practice, possibly to put a physician on part salary for a time, with the understanding that he may build up a private practice and the understanding that he will remain in the area, say, during the war emergency, or for at least a reasonable time. Funds to put physicians on such part salary probably could be obtained by the appropriate official state agency, state health department, or whatever it may be, from a federal agency, probably the United States Public Health Service. It is possible that funds could be made available. Another area has been suggested. Possibly some prepayment plan would be desirable, and in still other areas it may be necessary to bring the physician into the area on a full salary basis. Possibly, as has been suggested, some of these situations could be met only by assigning some one to the area from the Public Health Service. However, in all those situations—whatever is the best way of meeting those needs—we are desirous that the problem be studied and recommendations made by those responsible at the state level.

The question has been asked: Where are we going to get physicians to meet these needs? That of course is exceedingly difficult, and we cannot, I am sure, bring the level of medical care at a time like this up to what we would like to have it. There are many areas where there has never been what might be considered adequate medical care, but certainly we cannot expect to correct those at a time when there is a national shortage of physicians. There are some physicians, however, who have expressed a willingness to serve the nation during the war emergency, physicians who are not acceptable on account of physical defects or on account of age for commissions in the armed forces. Some of those will be available. Another group which I think we can particularly look to to supply numbers of physicians to go into some of these areas are the interns and residents of hospitals who are physically not qualified for service. The country over, there are going to be a considerable number of those probably twelve to fifteen hundred a year, who will be physically disqualified for service. Some of those young men are willing and anxious to serve the nation and will be glad to go into some of these production areas to render medical care. Others, I am sure, can be persuaded to do so and I think we should have that group particularly in mind and that we should take the initiative in attempting to point out to them the opportunities and the obligations to serve their nation during the war. At the present we are assembling a list of names of all the interns and residents in this country, who are serving at the present time, who do not hold commissions in the armed forces because they are physically disqualified. The names of those residents and interns will be sent to the respective state chairmen of the Procurement and Assignment Service with the suggestion and with the hope that personal contacts will be made with them in regard to the possibility of their serving the nation and serving the profession during this war emergency. This is, as has been said, probably the most difficult problem that has ever faced the profession. It is one, however, which at the present time we have the opportunity to meet in our own way and with our own methods and I am sure that we must not and will not fail to meet this challenge.

DR. KRESS: In connection with the matter of handling the problems of mushroom communities of which we have a goodly number in the state of California, I think it would be of interest to you to know that the Medical Service Organization of the California Medical Association and the California Physicians' Service has been the intermediary agent that has handled this problem, and in this way. The California Physicians' Service is now making contracts with the Federal Housing Administration for places for nurses and the necessary medical personnel in the communities. A recent city has grown up, Laredo City, across from San Francisco, had an influx of seven thousand, and across the bay a similar problem came into being. We emphasized that the California Physicians' Service will go in and place the necessary medical personnel to take the load off our local men and to carry on, however always in conjunction with the component county society. If you have medical service organizations of that type, you will find that they are the easiest and the best solution for that particular problem and in California I think we have a larger number of them than in practically any of the other states. We are happy to know that the plan is working out in splendid fashion.

DR HAROLD M. CAMP, Monmouth, Ill. Dr Barker asked for information from a few states, and as a secretary and editor, and state chairman for the Procurement and Assignment Service of one of the slacker states referred to by Colonel McCormack, I should like to give Dr Barker a little information that we have picked up. We have in Illinois something over 12,000 physicians. I might say, Colonel McCormack that our quota is approximately 33 1/3 per cent of the total number of physicians registered in the state of Illinois. We have 5 medical schools, 4 of which are accredited. We have 388 hospitals, most of which have essential men. We have 5,638 physicians under the age of 45 and our quota is something over 70 per cent of that total number. That is one reason we have not yet been able to make our quota, but we propose to do it by the end of the year. We have physicians living and practicing in 859 communities, and we have repeatedly made reappraisals of all our counties. We have 102 counties and we have 102 county committees of Procurement and Assignment, and we have repeatedly made appraisals since early this year. About once a month we send letters to all the county committees asking for definite information and requesting complaints. As a result of our more recent investigations we have 19 complaints. I think possibly 6 of those were referred to the governing board and Dr Lahey. Several of these were not justifiable. We had 1 complaint which was first registered by an energetic chamber of commerce secretary, undoubtedly at the request of his board of directors.

There happen to be 4 cities together without a county line, a corn field or anything more than a city street at the boundary line, with a population of 90,000 and across the river half a mile, on the Iowa shore, is another city, making a metropolitan area of 170,000 people. It so happened that the city making the complaint being 10,000 larger in population than the neighboring city on the Illinois side, had about half as many resident physicians as the smaller of the two cities and the complaint was that we were taking more physicians out of the larger city than out of the smaller 1 where we had the most doctors. It was rather unfortunate that out of 10 physicians physically disqualified in these 2 cities 8 came from the smaller of the 2. So the chamber of commerce and Procurement and Assignment was recommending the taking of too many men from this 1 city. We discovered that for a population of some 90,000 they have about 68 physicians remaining in the 2 cities at the present time. Their complaint went not only to Dr Lahey but also to the President of the United States, Mr. McNutt, the 2 United States Senators from Illinois and quite a bunch of Congressmen, the commanding general of the sixth corps area, the governor of the state and a few other dignitaries. All these copies eventually came back to our desk, asking that we make an investigation. That was the result of our reappraisal made, not piecemeal but through a number of sources.

We had 1 very unfortunate condition arise through no fault of Procurement and Assignment. In a county seat of 3,000 population were 2 physicians the same age. We made both of these men available, with the understanding that when 1 of them was examined and accepted the other automatically would be held as essential. The first man was examined and physically disqualified. He was told he was not eligible for commission for limited service. So we made the second man available and held the disqualified man as essential. The second man was examined and passed his examination and he was told to be in readiness to take off in about three weeks. A week before this man left, the first man had a telegram from General Uho, the Adjutant General, saying they had changed the order that he was accepted for general service and his commission was on the way, and he was given five days to go to camp. Here was a community without a doctor apparently. We got busy and largely through telephone service succeeded within three days in getting 2 physicians in this community to take the place of the 2 men who ultimately went into service.

I wanted to tell Colonel McCormack that out of some 12,000 physicians—we have 102 counties—8,000 or two thirds of them serving half the population of our state of a little over 8 million, are in 1 county. We have 4,000 in the other 101 counties or 1 physician for a thousand people. Our downstate counties are well stripped, and the men remaining there are going to be held as essential for the time being. We have had a serious problem in Cook County, with over 8,000 physicians, particularly because even though the Chicago Medical Society has 4,900 members there are 2,700 who are not members of the Chicago Medical Society in Cook County. Some of these fellows will have a dozen different locations in one year and consequently no one but the draft board can keep up with them. We finally went

through the draft boards to get a complete list of these men and they are now being processed at something like 100 or 150 a day.

DR HOLMAN TAYLOR, Fort Worth, Texas. When we began about six months ago to realize that we were about to dislocate too many doctors, the state medical association—not the Procurement and Assignment Service—began to make a realistic, not a statistical, survey. We wanted to find out how many doctors actually were at home, how many of them could render how much service, how many people there were to be served and how badly they needed doctors and we asked a conference of secretaries and the Procurement and Assignment Service to furnish us the data we needed. We gradually worked out a chart. The Procurement and Assignment assistant which Dr. Anderson is, can take the chart and find out what the ratio of doctors is in any group of counties. We have 254 counties. There are lots of areas there that don't have any doctors at all. We group them in the county societies. One society has 10 counties, another 9, another 6, 7, right along, but we take care of the counties individually and collectively. For instance to take 1 county, this is revised once each month. There are now 24 doctors in that county. The number deemed essential there is from 15 to 18. There is 1 Negro physician. We put great responsibilities on the Negro physicians down in Texas. We work with them beautifully believe it or not. There are 6 physicians there who can render the service of only 3. There are 3 not in practice and there is 1 osteopath. I can say 'osteopath' as state secretary. I can't say Procurement and Assignment chairman. We didn't care about him but we wanted to know he was there. We found out some surprising things about that. So the ratio in that particular county is 1 doctor to 1,788 people and so on down the line. Here is 1 county that has 1 doctor to 1,600 some odd people. What do the statistics show? That there are 18,334 people there. There are 3 physicians there now serving that many people. They have sent 1 doctor into the service and that 1 doctor brought that ratio to its high estate. It looks like a critical area but it isn't any more critical than it always was. They consider 3 can do the work. The doctors themselves say they can do that work and they are now getting all the work they can do.

Summarizing all of this, we have broken it down to some very interesting conclusions the first of which is that we have now only 3,436.5 active doctors in the state after we take out those who have entered the service. We found that 1 county had 9 doctors who could perform the service of 4 so we just say they have 4 doctors and not 9 because they haven't got 9 doctors as 1 or 2 of those have died from coronary conclusion as my cook calls it, since this thing started. In spite of the fact that we have greatly overrun our quota we find that in Texas, according to the census we have 1 doctor to 1,881 persons. That isn't greatly above 1,500, is it. But taking the estimated increase in population we have 1 doctor to 2,035 people. We revise this chart each month and we know just what we are doing.

Just a word about these critical areas. I don't believe a single area which has been reported to me as critical has been found to be critical on investigation. Most of those complaints come from interested people. As some speaker said today when you take a man's doctor he thinks there is a great depletion of doctors. We have had chambers of commerce, presidents of banks, district clerks and even Selective Service boards complain and raise a row about not having enough doctors. I sent 1 doctor down to an area from which they sent me a petition with 800 names. The president of the bank, the president of the chamber of commerce and the district judge came to see me as a committee. I got hold of a perfectly good doctor up in Michigan who wanted to come back home where it wasn't so cold. He was a graduate of Johns Hopkins. He went to the president of the chamber of commerce who said "We don't need any more doctors here. We have three doctors." Two doctors are past 70, 1 has coronary conclusion and the other has had a stroke. He discouraged the doctor from leaving there.

We are working out each of those areas realistically which brings me now to the only other observation I want to make. Somebody mentioned the matter of rationing tires for doctors. That is a serious problem for doctors in Texas, as it is in other states. There are doctors who have their cars laid up because they can't get retreads. There are doctors down there who are not given casings because they don't make calls. There isn't a doctor in the state of Texas who won't make a call if he is asked to make it. It is ridiculous that because he doesn't hold himself out as making calls he can't have tires for his car. With the gasoline restrictions coming on what are we going to do about this thing? Now I am speaking as state chairman of the Procurement and Assignment Service. We have got to visit county medical societies and these county

groups and find out just what the situation is in these alleged critical areas, and there isn't any way to do it in Texas except by automobile, except in a few instances. I have 1 automobile and it belongs to my wife. It is comparatively new and the casings are comparatively good. I will gladly keep on using my automobile, my rubber and my gasoline if they will give me some more and if they will let my wife use it. Somebody had better be doing something for these state chairmen who must get out in their areas to see what the situations are that are complained of and do something about fixing them. We can fill them. We can't fill them altogether from Texas because there isn't an area in Texas that isn't just about as critical as another area, and you can't borrow from Peter to pay Paul down there. You can't take from 1 pocket and put it in another, because it won't do any good. There is no money in either pocket. Somebody has to get out and rearrange these things. We can do it if we are given the facilities and we can't do it if we are not given the facilities.

SECRETARY WIST I am glad Dr Taylor mentioned this matter of transportation facilities or the lack of transportation facilities. There are various ramifications of that general subject. Down in Texas they never have any snow or not much. Whenever they have anything they have a lot of it but they don't have much snow. But in other parts of this country they have a lot of snow, and in certain parts they have a lot of mud. I don't know whether I have been overanxious or not, but I have been making the most strenuous effort to impress the Office of Price Administration with the fact that every physician in this country who actually lives in what might reasonably be called distressed areas—a distressed area, in my opinion, is one where there is 1 physician to cover a territory within a radius of from 7 to 25 miles. I don't care whether it is distressed under war circumstances or any other circumstances—I have been doing my best to change the regulation so that these men who have to travel on deep snow and muddy roads can serve the people who need medical service. I don't give a darn about the doctor's inconvenience. The doctors have shown they can stand as much inconvenience as anybody else

and they have done it. But the only answer I can get from Washington is that the doctors must undergo inconveniences like everybody else. Although I have continued to try to impress them with the fact that it is not the inconvenience of the doctor I am interested in and that the doctors themselves are interested in, but that it is the need of the people for medical service that is essential I have exhausted my resources. I got a last letter myself from the Office of Price Administration, and again they refer to inconveniences. I don't know whether I brought it up here with me or not. But I am telling you that nobody is going to be able to do anything about this tire situation Dr Taylor unless you can stimulate your Congressmen, and they disclaim ability to do it. I have a bunch of letters in my desk right now from Representatives in Congress who acknowledge their failure to make any impression whatever on this situation. The pressure on these people has got to come from where the people are. If you are going to get anything done about your tires, Dr Taylor, you are going to have to get some of those New Deal Congressmen busy and keep them busy until they can make some impression on this situation. I don't care whether you do it or whether you stimulate others to do it but it certainly needs to be done. These doctors tell me on the basis of years of experience that they simply do the work they are called on to do. The Office of Price Administration writes me that they have consulted the tire experts, and that the wear on snow tires is very little more than it is on any ordinary tire. The doctors tell me that just isn't so. I consulted some tire experts myself and they don't agree with the government experts. They tell me that the shimmying of snow tires on hard roads wears them out much faster than it does the ordinary tire. I am bringing this to your attention just for the purpose of telling you that if you need these things for the people themselves and for essential service nobody but doctors can deliver you have got to get the pressure from home. The American Medical Association has exhausted its resources in this matter and it is up to those people at home to bring the necessary pressure. It can't be done in any other way. (To be continued)

MEDICAL LEGISLATION

DISTRICT OF COLUMBIA

Change in Status—H R 7781 has passed the House defining the real property exempt from taxation in the District of Columbia. The bill exempts from taxation hospital buildings belonging to and operated by organizations which are not organized or operated for private gain including buildings and structures reasonably necessary and usual to the operation of a hospital, buildings belonging to and operated by schools, colleges or universities which are not organized or operated for private gain and which embrace the generally recognized relationship of teacher and student, and buildings belonging to and used in carrying on the purposes and activities of the Medical Society of the District of Columbia. Also exempted are the grounds belonging to and reasonably acquired and actually used for the carrying on of the activities and purposes of any institution or organization entitled to exemption, including additional grounds belonging to and forming a part of the property of such institutions or organizations as of July 1, 1942. The exemption of additional grounds, however, may be granted only on the filing of a written application to the commissioners of the District of Columbia, supported by an affidavit that such additional grounds are not held for profit or sale but only for the enlargement and expansion of the institution or organization. Institutions, organizations, corporations or associations owning exempt property must, on or before March 1, 1943 and on or before March 1 of each year thereafter furnish the commissioners of the District of Columbia a report, under oath, showing the purposes for which their exempt property has been used during the preceding year and a copy of the report must be forwarded to Congress by the commissioners.

MEDICAL BILLS IN CONGRESS

Bill Introduced—S 2902, introduced by Senator Davis, Pennsylvania, proposes to amend an act to regulate and improve the civil service of the United States by providing that no person shall be discriminated against in any case because of his or her

blindness or impaired visual acuity, in examination, appointment, reappointment, reinstatement, reemployment, promotion, transfer, retransfer, demotion, removal or retirement.

Change in Status—H R 7568 has passed the House and Senate, a bill proposing to discharge more effectively the obligations of the United States under certain treaties relating to the manufacture and distribution of narcotic drugs, by providing for the domestic control of the production and distribution of the opium poppy and its products, and for other purposes.

STATE MEDICAL LEGISLATION

New Jersey

Bills Introduced—S 358 to regulate the practice of nursing, proposes (1) to waive present registration requirements where applicant meets the requirements that were in existence at the time of his or her graduation from an approved school of nursing, or the requirements existing on April 1 1914 if the graduation was prior to that date. (2) the authorization of reciprocal registration of qualified Canadian licentiates. (3) to lower the age limit of students in approved nursing schools from 18 to 17½ years during the period of the war and for six months thereafter. A 412 proposes to authorize an approved medical school to give the required four courses of lectures of eight months either consecutively or in four different calendar years. A 413 proposes to amend the existing provision authorizing a lawfully qualified physician of another state to take charge temporarily of the practice of a New Jersey licentiate during his absence by conditioning such authorization on permission granted by the board of medical examiners and by providing that before a temporary licensee may enter on such practice he must submit proof that he can fulfil the requirements demanded in the other sections of the act relating to applicants for admission by examination or indorsement from another state and by providing that the temporary license shall be for a period of not less than two weeks nor more than four months. Such limited licensee must pay a fee of \$25 for his license.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ARIZONA

Annual Registration Due January 1—Every person practicing medicine, surgery or osteopathy in Arizona is required by law to pay annually on or before January 1, to the board of medical examiners, a renewal license fee of \$3. Any licentiate who does not renew his license as required above is to be penalized \$1 for each day that he practices without a renewal license, not to exceed \$50. The board of medical examiners is to revoke the license of any licentiate who fails to renew his license for three successive years.

ARKANSAS

District Meeting—The Ninth Councilor District Medical Society was addressed, among others, at the Hotel Scville, Harrison, December 2, by Drs. Melvin E. McCaskill on 'Abortion, Miscarriage, Missed-Abortion', Joseph F. Shuffield, 'Industrial Injuries', and Homer A. Higgins "Selective Service Medical Problems". All are from Little Rock.

Annual Registration Due On or Before January 1—All licentiates of the State Medical Board of the Arkansas Medical Society are required by law to register with the board on or before January 1 and at that time to pay such fee as has been set by the board. If a licentiate fails to pay the required annual fee before March 1 of any year his license to practice automatically expires but may be reinstated on the payment of all delinquent fees and a penalty of \$1 for each year, or part thereof, of delinquency.

CALIFORNIA

Annual Registration Due January 1—Every practitioner of medicine and surgery holding a license to practice in California is required by law to register annually, on or before January 1, with the secretary-treasurer of the board of medical examiners and at that time to pay a fee of \$2. Failure to pay the required fee within sixty days after January 1 works a revocation of a license and thereafter a license may be resumed only after application and the payment of a \$10 penalty. The required fee, however, is waived with respect to licentiates serving in the armed forces of the United States or in the United States Public Health Service.

Psychiatric Service in Venereal Disease Clinic—A psychiatric service has been made available in connection with the San Francisco city venereal disease clinic, 33 Hunt Street as a special field study project by the U. S. Public Health Service. A reeducation and readjustment program for females who offer a promiscuous sex history and who may spread venereal diseases will be provided. Those showing maladjustment will be referred to the psychiatric service, which will attempt to offer them a "potentiality of social and economic readjustment." The service will not attempt to assist in the socioeconomic readjustment of confirmed prostitutes. Patients referred to the clinic who, in the opinion of the personnel of the psychiatric service, are not amenable to psychiatric and case work treatment will be discharged from the clinic on preliminary interview. As far as the psychiatric service is concerned there will be no residence or financial requirements, and the service will be in a position to consider cases referred from outside sources. Arrangements will be made with various non-official agencies to provide funds in certain instances to carry out recommended psychiatric treatment plans. Attempts will be made to relocate the patients through cooperation of official and nonofficial agencies concerned. The medical director of the clinic is the chief of the division of venereal diseases, Dr. Richard A. Koch. The director of the psychiatric service of the clinic is Dr. Ernest G. Lion who is instructor of psychiatry at the Stanford University School of Medicine. The personnel of the psychiatric service will consist of a psychiatrist, a chief psychiatric social worker, an assistant psychiatric social worker and two clerks.

CONNECTICUT

Annual Registration Due During January—Every practitioner of medicine and surgery holding a license to practice in Connecticut is required by law to register during January, with the state department of health, and at that time to pay

a fee of \$2. Licentiates who have retired from active practice or who live out of the state must register annually but need not pay a fee. A practitioner failing to register is liable to a fine of not more than \$5.

GEORGIA

Campaign Against Hookworm—In a campaign against hookworm, the state department of public health is using a case finding plan to locate families suffering from the disease. Physicians, welfare directors, school superintendents and other agents are being questioned in an effort to trace all cases or suspected cases. A concentrated program will be carried on between December 15 and March 15.

Statewide Quarantine on Venereal Diseases—A quarantine of all persons with venereal disease has been declared by the Georgia Department of Public Health in an order establishing regulations for control of venereal diseases and providing compulsory detention centers. According to *Georgia's Health*, the quarantine was made applicable to "all persons who have been directly exposed to venereal disease as well as to those actually infected. No isolation posts or quarantine stations have been established yet but one or more will be put in operation as quickly as possible in cooperation with authorities of the counties where they are located. These will be financed largely by the federal government. The state board of health will provide for transporting persons to the isolation posts and when they are cured will return them to any place in the state to which they wish to go. The state board bulletin reports that Georgia now has an epidemic of venereal diseases of such proportions that it is a menace to public health and a threat to an ill out war effort. The order was adopted in response to requests of army and federal public health officials for measures to protect soldiers from venereal diseases.

ILLINOIS

Dr. Stevenson Receives Award—Dr. Walter D. Stevenson, Quincy, first president of the Mississippi Valley Medical Society, was presented with the society's distinguished service award for 1942 during the recent annual meeting in Quincy. The award is given annually to an active member of the society for "unusual and distinguished service to the medical profession." Dr. Stevenson is a charter member and president of the board of trustees of the society and served as its first president, in 1935.

Chicago

Meeting of Bacteriologists—The Society of Illinois Bacteriologists held a meeting at the Chicago Film Union December 11. The speakers were Willard Turner, Ph.D., on 'Bacteriological Aspects of Egg Drying', Henry R. Kraybill, Ph.D., 'Dehydration of Meats', and Milton Levine, Ph.D., 'Toxicity of Human Plasma'.

Old Wesley Hospital Dedicated as Venereal Disease Unit—Special ceremonies marked the opening and dedication of the Chicago Venereal Disease Hospital in a seven-story building at 2449 South Dearborn Street November 29. The old Wesley Hospital. The speakers include Vice President Henry A. Wallace, Dr. Thomas Parran, surgeon general of the U. S. Public Health Service, and representatives of the Army and Navy. Federal and city funds totaling \$425,000 will finance the institution for the first year. Dr. Herman N. Bindesen, president of the Chicago Board of Health and health commissioner, will be in charge of the institution until he chooses a permanent director.

Meeting of Association for Crippled—Mr. George H. Williamson was chosen president of the Illinois Association for the Crippled Inc. at its sixth annual meeting at the La Salle Hotel November 27. Mr. Jules L. Brady and Miss Thecla Donat were chosen vice presidents. Mrs. Arthur C. Bachmeyer, secretary, and Mr. William S. Turner, treasurer. Mrs. Lola M. Armstrong is the executive secretary. All are of Chicago. Dr. Edward L. Compere delivered the presidential annual message at the luncheon session and E. Jay Howenstein, Elyria, Ohio, executive secretary of the National Society for Crippled Children of the United States of America Inc., discussed 'New Federal Rulings and Pending Legislation Affecting the Physically Handicapped'. The scientific program was devoted to a symposium on 'Marshalling Resources to Utilize Physically Handicapped Workers'.

KANSAS

New State Ophthalmologist—Dr. William W. Reed, Topeka, on November 1 was appointed state supervising ophthalmologist to the Kansas State Board of Social Welfare. Dr. Reed succeeded Dr. Hazen L. Kirkpatrick, Topeka, who recently resigned to accept a commission as captain in the medical corps of the U. S. Air Corps.

LOUISIANA

Director of Maternal Welfare Joins Medical School—Dr Virginia E. Webb, chief, division of maternal and child welfare of the state department of health, New Orleans, has recently been appointed clinical assistant in the department of obstetrics and gynecology at the Louisiana State University School of Medicine, New Orleans.

Annual Renewal Due January 1—Every practitioner of medicine and surgery holding a certificate to practice in Louisiana is required by law to have his certificate renewed annually, on or before January 1, by the secretary-treasurer of the state board of medical examiners, and at that time to pay a fee of \$2. The board may by unanimous vote revoke any certificate not renewed.

MINNESOTA

Annual Registration Due During January—Every practitioner of medicine and surgery holding a license to practice in Minnesota is required by law to register annually during January, with the secretary of the board of medical examiners, and at that time to pay a fee of \$2. A licensee who practices without renewing his license is guilty of a misdemeanor and is liable to prosecution.

The Ninth Bell Lecture—Dr Thomas J. Kinsella, clinical assistant professor of surgery, University of Minnesota Medical School, Minneapolis, delivered the ninth annual Bell Lecture before the Hennepin County Medical Society, December 7, under the joint auspices of the Hennepin County Medical Society and the Hennepin County Tuberculosis Association. His subject was "Modern Surgical Treatment of Tuberculosis."

Society News—Dr John L. Emmett, Rochester, addressed the Ramsey County Medical Society in St. Paul, November 3, on "Newer Drugs in the Treatment of Urinary Infections" and Dr Arnold Schwytzer, St. Paul, gave a clinical talk on "Abdominal Pain."—The Minnesota Academy of Medicine was addressed in St. Paul, October 14, by Drs. Moses Barron and Owen H. Waugusteen, both of Minneapolis, on the medical and surgical management of peptic ulcer, respectively.

MISSOURI

Dr Julianelle Goes to New York Research Institute—Louis A. Julianelle, Ph.D., associate professor of applied bacteriology and immunology in ophthalmology, Washington University School of Medicine, St. Louis, and chairman of the trachoma commission there, has been appointed chief of the division of infectious diseases of the Public Health Research Institute of the City of New York, Inc. Dr Julianelle received his doctor of philosophy degree at the University of Pennsylvania, Philadelphia, in 1922. He served there as instructor in bacteriology until 1924 when he joined the staff of the Rockefeller Institute Hospital, New York, as assistant. Later he served as bacteriologist and associate there, joining the Washington University faculty in 1930.

NEW YORK

Annual Registration Due January 1—Every practitioner of medicine and surgery in New York is required by law to apply annually, on or before January 1, to the secretary of the board of medical examiners for a certificate of registration, on application forms furnished by him and to pay at that time a fee of \$2. The law authorizes the secretary of the board to permit secretaries of duly incorporated medical societies to act as his representatives to receive and transmit to him such applications and fees. Practitioners are liable to severe penalties for failing to register and for continuing in practice thereafter.

New York City

Harvey Lecture—Dr John R. Paul, professor of preventive medicine, Yale University School of Medicine, New Haven, Conn., will deliver the third Harvey Society Lecture of the current series at the New York Academy of Medicine, December 17, on "Polymyositis."

Report of Public Health Research Institute—A report has been issued by the Public Health Research Institute of the City of New York, Inc., for the period July 1, 1941 to June 30, 1942, during which time it carried on health research for the city under a temporary contract. The ten-year contract calling for payment of \$100,000 annually by the city to the institute did not go into effect until July 1 of this year. Otto A. Bessey, Ph.D., formerly research associate in pathology and associate in biologic chemistry, Harvard Medical School, Boston, has been named director of the institute for the duration of the war, replacing Dr. Ralph S. Muekenfuss, who has been called into army service. Dr. Muekenfuss' position as director of the bureau of laboratories of the city department

of health is being filled by Dr. Wheelan D. Suthiff as acting director. Dr. Bessey is also chief of the division of nutrition and physiology of the institute. A report by Dr. Thomas M. Rivers, director of the Rockefeller Hospital and chairman of the scientific council of the institute, stated that one of the objects of the division of nutrition and physiology "is determination of the amount, type and degree of nutritional inadequacy in the population of the city of New York, to determine the nature and extent of the handicaps from such inadequacy, and to develop and suggest corrective measures."

NORTH DAKOTA

Annual Registration Due January 1—Every practitioner of medicine and surgery holding a license to practice in North Dakota is required by law to register annually on or before January 1, with the secretary-treasurer of the board of medical examiners, and at that time to pay a fee of \$5 if a resident of North Dakota, or \$2 if a nonresident. A practitioner may not lawfully practice if he has not registered. If he does so his license may be revoked and can be reinstated on the payment of unpaid fees and \$0.50 for each month of default.

OHIO

Doctors' Orchestra Suspends Activities—Because 30 per cent of its members are now serving in the armed forces the Doctors' Symphony Orchestra has temporarily suspended its activities after a successful career of sixteen years. Founded as the Physicians' Orchestra by nine physicians and two medical students in November 1926 it was transformed into the Doctors' Orchestra, composed of physicians and dentists. Two years later the personnel had increased to symphonic size and the present title, the Doctors' Symphony Orchestra, was assumed. The orchestra has played for hospitals and medical and dental societies in Akron, Barberton, Wadsworth, Canton, Columbus and other communities. Benefit concerts have been given for the City Hospital, Akron, the Wadsworth Municipal Hospital and the Citizens Hospital, Barberton. In all one hundred and three appearances have been made in eleven Ohio cities and towns. According to the *Bulletin* of the Summit County Medical Society, the suspension of activity is not permanent and will depend on the duration of the war. Dr. Alexander S. McCormick, Akron, has been director since the establishment of the orchestra. The concertmaster is Dr. H. Heuninger, D.D.S., Akron, and the assistant concertmaster, Dr. Arthur Dobkin, is now in service overseas as a major in the Army.

PENNSYLVANIA

Annual Registration Due January 1—Every practitioner of medicine and surgery holding a license to practice in Pennsylvania is required by law to register annually on or before January 1, with the board of medical education and licensure in the department of public instruction and to pay a fee of \$1 or such fee as may be fixed by the department of public instruction. A practitioner who fails to register and who continues to practice is liable to a fine of from \$10 to \$100.

Society News—Dr. Helen B. Taussig, Baltimore, will address the Harrisburg Academy of Medicine, December 15, on "Significance of Changes in Size of Heart in Rheumatic Fever and Congenital Malformations of the Heart in Relation to the Growth of the Child."—Dr. Lloyd F. Craver, New York, discussed "Cancer and Allied Disorders" before the Dauphin County Medical Society, December 1, in Harrisburg. —Dr. Walter I. Lillie, Philadelphia, discussed "Vascular Changes in Hypertensive Disease" before the Reading Eye, Ear, Nose and Throat Society, November 18.

Philadelphia

Special Lectures—Dr. Stanhope Bayne-Jones, professor of bacteriology, Yale University School of Medicine, New Haven, Conn., and colonel in the medical corps of the army, will lecture before the College of Physicians of Philadelphia and the Philadelphia County Medical Society, January 13, on "Tetanus." Dr. Paul C. Colonna, professor of orthopedic surgery, University of Pennsylvania School of Medicine, will deliver the Nathan Lewis Hatfield Lecture before a joint meeting of the College of Physicians and the county medical society, February 3. His subject will be "The Role of Surgery in the Chronic Arthritic Patient."

TEXAS

Annual Registration Due January 1—Every practitioner of medicine and surgery holding a license to practice in Texas is required by law to register annually on or before January 1, with the state board of medical examiners and at that time to pay a fee of \$2. If a practitioner fails to renew his registration within sixty days after January 1, his license is suspended.

GENERAL

Medal Awarded to Sister Kenny—Sister Elizabeth Kenny, who has established her headquarters in Minneapolis, was presented with the annual medal of *Parents Magazine*, awarded for outstanding service to children.

Bacteriologists Cancel Meeting—The annual session of the Society of American Bacteriologists scheduled to be held in Columbus, Ohio, December 28-30, has been canceled at the request of the Office of Defense Transportation and the science committee of the National Resources Planning Board. The council will consider the possibilities for a meeting in 1943. It was stated. The program for the canceled meeting has been printed and will be sent to members. Abstracts of the papers which were to be presented at the meeting this year will be printed in the January number of the *Journal of Bacteriology*.

Urology Award—The American Urological Association offers an annual award 'not to exceed \$500 for any essay (or essays) on the result of some specific clinical or laboratory research in urology. The amount of the prize is based on the merits of the work presented and if the committee on scientific research deems none of the offerings worthy no award will be made. Competitors shall be limited to residents in urology in recognized hospitals and to urologists who have been in such specific practice for not more than five years. The selected essay will appear on the program of the forthcoming meeting of the association, May 31-June 3 at the Hotel Jefferson, St. Louis. Essays must be in the hands of the secretary, Dr. Thomas D. Moore, 899 Madison Avenue, Memphis, Tenn., on or before March 1, 1943.

Prize for Work on Glaucoma—The National Society for the Prevention of Blindness announces that a prize of \$250 will be awarded for the most valuable original paper during 1943 adding to the existing knowledge about the diagnosis of early glaucoma. The award will be made by the society with the guidance of an ophthalmologic committee composed of Drs. Arnold Knapp, Manuel Uribe Troncoso and Mark J. Schoenberg, all of New York. Papers may be presented by any ophthalmologist, student in ophthalmology or research worker of the western hemisphere and may be written in English, French, German, Italian, Spanish or Portuguese but those written in the last four named languages should be accompanied by a translation in English. Papers should be in the office of the National Society for the Prevention of Blindness, 1790 Broadway, New York, by September 15.

Special Society Elections—Dr. Felix J. Underwood, Jackson, Miss., was chosen president elect of the American Public Health Association at its recent meeting in St. Louis and Dr. Allen W. Freeman, Baltimore, was installed as president. Dr. Reginald M. Atwater, New York, is the secretary. —Dr. Franklin P. Gengenbach, Denver, was named president elect of the American Academy of Pediatrics at its meeting in Chicago in November and Dr. Borden S. Vieder, St. Louis, was inducted into the presidency. Dr. Clifford G. Grulke, Evanston, Ill., is the secretary. The academy will not hold a meeting in 1943. —Col. Lucius A. Salisbury, M. C. U. S. Army (National Guard), New York, was chosen president elect of the Association of Military Surgeons of the United States at its annual meeting in San Antonio, Texas, November 7 and Captain William L. Mann, medical director, U. S. Navy, Washington, D. C., was installed as president. Col. James M. Phalen, M. C. U. S. Army, retired, Army Medical Museum, Washington, D. C., is the secretary.

Jacobi Fellowship Available—The Women's Medical Association of New York offers a Mary Putnam Jacobi Fellowship for medical research of \$1,000, available Oct. 1, 1943. It is open to any woman doctor, American or foreign who is a graduate of a reputable medical school. Applications must be filed with the secretary of the committee by March 1 and must be accompanied by statements of persons other than the candidate as to health, educational qualifications and previous work. The applicant herself should state the problem she proposes to investigate and send her photograph. As it is not practicable for the secretary to write for letters about candidates, applicants should send with their applications sufficient data to enable the committee to judge of their respective merits. The recipient of the fellowship will be expected to give full time to the study of her problem and to make a report for publication at the completion of her research. Application blanks may be obtained from the secretary of the committee, Dr. Phebe L. Du Bois, 150 East 73d Street, New York.

Association for Advancement of Science—The one hundred and eleventh meeting of the American Association for the Advancement of Science will be held in New York, December 28-January 2. Registration will be at the Commodore Pennsylvania, Edison and Henry Hudson hotels. Irving Lang-

muir, Sc.D., associate director of the Research Laboratory of the General Electric Company, Schenectady, N. Y., will deliver his address as retiring president Monday evening, December 28. On Tuesday John F. Tate, Ph.D., dean of the College of Science, Literature and Art and director of the university college, University of Minnesota, Minneapolis, will deliver the twenty-first annual lecture under the joint auspices of the association and the society of Sigma Xi on 'Scientists in War and Peace.' In addition to the fifteen sections of the association about forty-four affiliated and associated societies and other cooperating organizations will participate in the session. The Section on Medical Sciences will meet December 28-30. One session will be devoted to a symposium on 'Carbohydrate Metabolism,' under the auspices of the section and the New York Section of the Society for Experimental Biology and Medicine. Two sessions on tropical medicine will be jointly sponsored by the section on medicine, the American Society of Parasitologists, the National Malaria Society, the American Society of Tropical Medicine and the New York Society of Tropical Medicine. At the first session papers will be presented by Col. James S. Simmons, M. C. U. S. Army, Office of the Surgeon General, Col. Richard P. Strong, M. C. U. S. Army, Lieut. Col. Thomas F. Mackie, M. C. U. S. Army, and Dr. Ann Greck, New York. Arthur H. Compton, Ph.D., Chicago, president of the association will present the fifth Theobald Smith Award at the conclusion of this session. At the second meeting, the speakers will be Col. George R. Callender, M. C. U. S. Army, Malcolm H. Soule, Sc.D., Ann Arbor, Mich., Dr. Lowell I. Coggeshall, Ann Arbor, and Dr. Wilbur A. Sawyer, New York. After this session Dr. Wade W. Oliver, Brooklyn, vice president of the association for the Section on Medical Sciences will deliver his retiring address on 'The Man Who Lived for Tomorrow.' On Tuesday evening, the medical section will join with the New York Society of Tropical Medicine for the presentation of the Theobald Smith Lecture by Dr. M. Ruiz Castañeda, Hospital General Departamento de Investigaciones Medicas, Mexico. Included among the speakers at the final session of the section on Wednesday will be Drs. Charles C. Macklin, London, Ont., Canada; Walter S. Hartroit, London, Ont.; Eric Miles Atkinson, New York; Benjamin Karpman, Washington, D. C.; Harry Eagle, Baltimore; and Edward C. Rosnow, Rochester, Minn., and Jesse P. Greenstein, Ph.D., Bethesda, Md.

The U. S. Public Health Service will sponsor a symposium on 'Drug Intoxication and Drug Addiction' which will be presented at six sessions to be held on Monday, Tuesday and Wednesday. One session will be devoted to 'Barbiturates, Bromides and Chloral' one to 'Cocaine, Marijuana and Peyote,' and four to 'The Opiates.' The symposium will close with a public meeting Wednesday afternoon at which Dr. Thomas Parran, surgeon general, U. S. Public Health Service, will introduce Dr. Lawrence Kolb, assistant surgeon general, division of mental hygiene of the service who will deliver an address entitled 'Drug Addiction as a Public Health Problem.'

The Section on Agriculture and the American Society for Horticultural Science will present a joint symposium on nutrition December 30 with the following speakers: Leonard A. Maynard, Ph.D., New York; Conrad A. Elvehjem, Ph.D., Madison, Wis.; Richard Bradford, Ph.D., Ithaca, N. Y.; John R. Magnus, Ph.D., Bureau of Plant Industry, U. S. Department of Agriculture, Beltsville, Md.; and Lydia I. Roberts, Ph.D., Chicago. The American Science Teachers Association will meet December 30. At the sessions of the American Association of Scientific Workers, December 29-30, the speakers will include Dr. Morris Fishbein, Chicago, Editor of *THE JOURNAL*, on 'Medicine in the Armed Forces and on the Home Front.' Another feature will be a program on 'War Science in the United Nations.'

CORRECTION

Panel Discussion on Ulcer—In the Abstract of Question Period following the Panel Discussion on Ulcer beginning on page 824 in *THE JOURNAL*, November 14, Dr. Asher Winkelstein desires to make the following corrections in some of his discussions. Dr. Winkelstein says that in his second discussion 'intradigestive' should read 'interdigestive', his third discussion should read 'milk drip form of therapy' instead of 'milk form of therapy', his fourth discussion should read 'reduced' instead of 'produced,' 'milk' should be inserted before 'bicarbonate' and following 'phosphate' should be inserted to p. 35 and from 650 to 'should be omitted in his fifth discussion the 'h' should be deleted from Dr. Berg's name, 'not' should be omitted before the word 'cut' 'subphrenic anterior' should be used instead of 'subinterior,' and finally 'which may lead to harmful procedures in the abdomen' should be omitted.

Nov 7, 1942

Medical Aid in New Guinea

A medical officer in the Australian forces who spent several weeks in the front line in New Guinea, until his leg was shattered by a Japanese bullet, has given a vivid picture of medical conditions in the Owen Stanley range. The troops, having no tents, slept in the open or under shelters of thatch made by the natives. They were always wet. The sun shone for a few hours every morning but rain fell in torrents every afternoon. The men lived on biscuits, bully beef and water. They had tea but could not boil water, as flames at night or smoke by day would give away their positions to the enemy. They were nearly always hungry. Fortunately there were no mosquitoes in the highlands and thus there was little malaria and no dengue. Most of the wounds were caused by rifle or machine gun fire and a few by mortar fire. The doctors were very short of drugs. All supplies had to be brought to the front line by porters, and preference was given to ammunition and food over medical supplies.

The regimental aid-post at first had no tents, but the medical officer managed to get three two-men tents to cover the worst cases. Twice the Japanese fired through the tents once when the medical officer was in the middle of an amputation. The wounded were wounded again as they lay in the tents. Light casualties had to walk along the trail. Severe casualties were carried on stretchers by Papuan boys, usually six to one stretcher, but on difficult terrain ten or more were required. The medical officer praises the work done by these boys as 'beyond all description'.

Live Shell Removed from a Man's Thigh

In a recent speech Dr Donald Hall, chairman of the Royal County Hospital, told of a man brought to the hospital with a thigh injured during a recent air raid. Under the wound of entry a sharp pointed object could be felt. At the time of injury the enemy had dropped all their bombs and were headed home with their guns blazing. It was decided that the object therefore was not a bomb fragment and was thought possibly to be part of a fractured femur. X-ray examination however, revealed that an unexploded cannon shell was embedded in the tissues. The bomb disposal unit was called and the officer identified the shell from the roentgenogram as of the armor piercing variety which explodes on impact. What was to be done? If the shell exploded, at best the man would lose his leg, which would be shattered, very likely he would lose his life. If the shell exploded during the operation for its extraction, the surgeon and every one in the operating room ran great risks, especially for loss of eyesight. The removal was necessary, danger or no danger. The patient was left in blissful ignorance and the surgeon, his assistant, the anesthetist and the nurses got to work. Swiftly and successfully the surgeon performed the most delicate and dangerous operation of his career and removed the shell. Within half an hour of leaving the ward the patient was back in bed. The name of the surgeon was not revealed. During the operation, according to this report an assistant surgeon appeared at the door of the operating room to inquire what were his prospects for promotion to the senior staff.

Training the Limbless to Return to a Full Life

This greatest of wars involves an enormous loss of limbs as well as of lives. At a meeting held at the Mansion House under the presidency of the lord mayor, Mr Bevin, minister of labor, spoke on the employment of limbless persons injured in the war. The employment on full wages of an ex-soldier so injured

should be regarded not as a virtue but as a duty and honor. The government had determined to establish a national rehabilitation scheme, which would be one of the greatest social services ever established in this country. They would provide training for any citizen who was injured.

Sir Walter Wormseley, minister of pensions, said that there had been enormous improvements in the artificial limbs issued. American visitors to Roehampton Hospital had declared that we were even ahead of the United States.

Mr R Langdale Kelham, chief limb surgeon to Roehampton Hospital, said that the greatest obstacle to a return to normal life was the idea that a patient who had lost his leg was necessarily a cripple. He asked the meeting to note the normal appearance, gait, activity and expression of those whom he asked to walk across the platform. The first was a lieutenant commander, still serving in the Navy, whose leg had been amputated below the knee. Then came 5 others who had undergone the same operation. Among them was a schoolgirl injured in an air raid and now back at her work. She could walk, run, skip and ride a bicycle.

New Scheme for Treatment of Tuberculosis

In the House of Commons Mr E Brown, minister of health, announced a new scheme for the treatment of tuberculosis based on a report by a committee appointed by the Medical Research Council at his request. To facilitate early diagnosis he has obtained priority for the supply of some thirty sets of equipment for mass roentgenography, which will be allocated to the large centers of population where they can be used to the best advantage. Training of the necessary expert staff has been arranged. The extended arrangements will need additional beds in sanatoriums which have been arranged for. Immediate needs in regard to trained nurses can be met only by better distribution. It is important that those who give up their work temporarily to be treated under the new scheme should no less in their own interest than in that of the public health be able to do so without anxiety as to the maintenance of their dependents. Local authorities are therefore being authorized to grant financial assistance in such cases to provide for the maintenance of the dependents and avoid the break up of the home while the breadwinner is under treatment.

Fatigue Fracture of the Tibia

The curious condition of fatigue fracture of the tibia appears to have been first described only three years ago by Roberts and Vogt (*J Bone & Joint Surg* 21 891 [Oct] 1939). In the *British Journal of Surgery* for July (which is late in publication because after it had gone to press the whole of the type and the illustrations were destroyed by enemy action and had to be replaced) J Blair Hartley reports as many as 14 cases. This indicates that the condition is not so rare as might be supposed and must have been overlooked in the past until attention was drawn to it. Generally there is no history of injury and certainly none of violence likely to cause a fracture. The only constant symptom is pain on standing on walking or after walking. This may be behind the knee or over the inner aspect of the upper third of the tibia. In 5 of Hartley's patients slight swelling could be detected on the inner aspect of the upper end of the shaft of the tibia. The condition always occurs in children or adolescents. The oldest patient in Hartley's series was 20 years of age. The average age was 3 years, in Roberts and Vogt's series it was 10.9 years. Radiologically the lesion is $1\frac{1}{2}$ to $3\frac{1}{4}$ inches below the epiphyseal line depending on the age and height of the patient. There is always callus, usually on the inner aspect, occasionally on the outer. The early changes may be overlooked unless the roentgenograms are faultless. In the early cases a tiny nick is seen in the cortex of the tibia, either medially or laterally or both. In the lateral view there is seen beyond the cortex

posteriorly a tiny mass of callus. Later, extending forward horizontally within the tibia from the callus is seen an area of osteoporosis or, in a mild case, an ill defined zone of osteosclerosis. Under rest the callus increases and the osteoporosis is replaced by dense bone, the callus becomes organized and in the ensuing months gradual repair occurs.

No case in Hartley's series which has been treated by immobilization failed to progress to cure. Investigation should be made for causes of abnormal stress and strain. There is evidence that the affected area of the tibia is subject to a good deal of strain. Hartley's belief is that the condition is a fatigue fracture due either to faulty structure of the bone at the area of maximum strain or to abnormal strain at a site already subject to considerable stress. There is similarity to march fracture of the metatarsals both in radiologic appearance and in rate and method of healing. It is essentially a "fatigue dystrophy" such as has been described by Prof Karl Henschen of Basle. It is definitely not due to infection.

Britain's War Effort

Mr Bevin, minister of labor has described in a broadcast Britain's war effort in production. Out of 33 million people in Great Britain between the ages of 14 and 65 years we mobilized for service more than 23½ millions of men and women, who were now on full time work for the nation in one capacity or another. There were also great numbers rendering voluntary service. When an account was taken of these there were left something less than 3 millions, which included children the sick, crippled and aged. But we must measure our mobilization not only in numbers but also in terms of the energy exerted. For more than three years great numbers of our factory workers have been toiling between sixty and seventy hours a week and today are working on the average fifty-six hours. The British people had consented to the highest mobilization of any nation in the world at this moment. Taxation that would seem unbelievable in peacetime had been cheerfully accepted to pay for the struggle. For the same purpose and in the same spirit people had stinted themselves and lent the state in small savings \$800,000,000.

Food Rationing for Diabetic Patients

Early in the war the government appointed a committee of experts to consider what modification of the rationing system would be necessary for invalids, and particularly for diabetic patients. Those not on insulin could not, like normal persons substitute more carbohydrate foods bread, potatoes and the like for the restricted protein and fat. Patients on insulin were in a better position because they could increase the dosage, if necessary, to compensate for less protein and fat. However, no distinction was made between the two groups, and it was decided that all diabetic patients by giving up their sugar could obtain extra protein, in the form of meat, and fat rations on producing a doctor's certificate. Subsequently extra cheese (12 ounces a week, later increased to 16 ounces) was granted and extra milk (1 pint daily) could be prescribed. Two extra fat rations of 6 ounces a week of butter or margarine are allowed, making a weekly total of 18 ounces of butter or margarine and 2 ounces of cooking fat. The protein ration scheme amounts to 40 ounces of meat, 12 ounces of cheese, 4 ounces of bacon and up to 7 pints of milk weekly. In addition, there are occasional eggs, fish and poultry. Thus the animal protein allowance is very liberal.

Diabetic patients threatened with ketosis suffer from nausea and vomiting and may be unable to take their usual diet. They must take carbohydrate to balance their insulin. As sugar and sugared drinks are usually the best form in which to take carbohydrate, an emergency supply can be obtained on presenting a medical certificate at the local food office. One and one-half pounds is allowed at once in exchange for the meat, bacon fat and cheese coupons for the next week.

Indian War Casualties

At the Indian council of state, held at Delhi, the government spokesman stated that Indian war casualties up to September 23 numbered about 100,000 and were made up of 2,096 killed, 8,521 wounded, 2,938 prisoners and 84,833 missing. The missing were those about whom the government had no information that they were prisoners. Some 70,000 were still untraced in Malaya and the Far East generally and about 12,000 in Libya.

BRAZIL

(From Our Regular Correspondent)

Oct 15, 1942

Brief Items

Dr J. Moreira da Fonseca, professor of medicine at the University of Rio de Janeiro, has been elected president of the National Academy of Medicine. Professor Moreira da Fonseca is well known for his studies on the reticuloendothelial system, particularly in tropical diseases.

The National Academy of Medicine held a special meeting to honor the memory of Dr. Francisco Fajardo, a physician of Rio de Janeiro who died in 1907 from anaphylactic shock after the second injection of a mixture of antipneumococcus serum and vaccine. Dr. Fajardo was a pioneer in bacteriology, parasitology and tropical medicine in Brazil. He founded in 1895 the bacteriologic laboratory of the health department of Rio de Janeiro and began the study of Brazilian mosquitoes, the description of which was published in medical periodicals of Great Britain and Germany. Theobald of the British Museum of London honored Dr. Fajardo by giving two new species of mosquitoes his name (*Stegomyia fajardoi* and *Culex fajardoi*).

The first Brazilian Congress for the Prevention of Blindness was held from July 1 to 4 in this city. Many contributions regarding the subjects of good illumination and eye hygiene were presented. A feature of the congress was the presence of Dr. Matthew Luckiesh of the General Electric Laboratories of the United States, who read a paper on Light and Vision.

The Brazilian army medical corps has organized an emergency course of military medicine which is being given in connection with the medical school of the University of Rio de Janeiro. Surg. Gen. Dr. Souza Ferreira has appointed Col. Dr. E. Marques Porto to act as director of the course. The training work has just begun, with a registration of two hundred and seventy physicians. A second group of physicians is being organized, to begin the training work in August.

Deaths

Dr. Pedro Ernesto, a noted surgeon and founder of the Pedro Ernesto Hospital, died at the age of 56. Dr. Pedro Ernesto was mayor of Rio de Janeiro from 1931 to 1935. He visited the United States a few months ago.

Marriages

RALPH JOSEPH RAGOSTA, Brooklyn, to Miss Aline Margaret Baldwin at Alexandria, La., September 16.

DONALD VINCENT HIRST, Durham, N. C., to Miss Katherine Louise Binder at Leonia, N. J., June 26.

JAMES W. AGNEW, Iowa City, to Miss Alice Marie Kline of Knoxville in Cedar Rapids, July 21.

RICHARD E. H. PHELPS, State Center, Iowa, to Miss Priscilla Imlay of Black Earth, Wis., July 24.

CLAUDE B. ROGERS to Miss Madeline Seger, both of Earlville, Iowa, at Nashua, July 29.

SAMUEL MAULDIN WILLS to Miss Helena Gertrude Bengtson, both of Minneapolis, July 18.

HERMAN B. KATZMAN to Miss Florence C. Kahan, both of Brooklyn, June 28.

Deaths

Reuben Peterson ⊕ Duxbury, Mass., Harvard Medical School, Boston, 1889, in general practice at Grand Rapids, Mich., from 1890 to 1898, became associated with the University of Michigan Medical School, Ann Arbor, in 1901 as professor of obstetrics and gynecology, the fourth man to head that department since the founding of the university in 1850, a position he filled until 1931, when he retired with the title of emeritus professor, professor of gynecology at the Post-Graduate Medical School of Chicago from 1898 to 1901, carrying a concurrent appointment as assistant professor of obstetrics and gynecology at Rush Medical College, Chicago, secretary of the Section on Obstetrics and Diseases of Women, 1895-1896, chairman of the Section on Obstetrics, Gynecology and Abdominal Surgery, 1919-1920, and member of the House of Delegates in 1907 and in 1919 of the American Medical Association, specialist certified by the American Board of Obstetrics and Gynecology, Inc., one of the founders and a fellow of the American College of Surgeons, president in 1911, fellow from 1897 to 1931 and since then honorary fellow of the American Gynecological Society, honorary fellow of the Detroit Obstetrical and Gynecological Society and the Edinburgh Obstetrical Society, honorary fellow of the Washtenaw County Medical Society and president in 1902 honorary fellow of the Michigan State Medical Society and president in 1915 served as a major in the medical corps of the U S Army during World War I, medical director of the University Hospital, Ann Arbor, from 1912 to 1918 at one time medical director and owner of the Ann Arbor Private Hospital served as medical adviser to the governor of Michigan from 1917 to 1919, formerly a member of the board of health of Ann Arbor, received the honorary doctor of science degree from the University of Michigan in 1936, in 1931 his portrait was presented to the University of Michigan by a group of his former assistants, editor of "Peterson's Obstetrics" a volume published in 1907, author of "A Manual for a Demonstration Course in Obstetrics" first edition published in 1930 and second edition published in 1937, aged 80 died November 25

Le Roy Augustus Wilkes ⊕ Trenton N J, University of Pennsylvania School of Medicine, Philadelphia, 1910, appointed executive officer of the Medical Society of New Jersey in 1933, member of the American Public Health Association, the American Academy of Pediatrics, on the executive committee of the New Jersey Health and Sanitary Association, on the executive board of the New Jersey Welfare Council and of the New Jersey and Mercer County Tuberculosis Leagues, specialist certified by the American Board of Pediatrics, Inc., formerly practiced pediatrics in Philadelphia, where he was a medical school inspector, had been connected with the University, Children's, Polyclinic and Presbyterian hospitals and was attending pediatrician to the Pennsylvania State Tuberculosis Dispensary number 17 from 1912 to 1917 from 1917 to 1920 director of the child hygiene division of the Bridgeport (Conn.) Department of Health, an appointment by the U S Public Health Service, medical director of the Trenton (N J) Board of Education from 1920 to 1923 during 1923 and 1925 he was in Austria and Germany at which time he was medical director of the Austrian Child Health Program of the Commonwealth Fund of New York was director of the student health services of the University of Texas, Austin, 1926-1927, director of medical service of the American Child Health Association from 1927 to 1933, acting editor of the *Journal of the Medical Society of New Jersey*, aged 59, died suddenly, November 29, of cerebral hemorrhage

Howard Clinton Frontz ⊕ Huntingdon Pa., University of Pennsylvania Department of Medicine, Philadelphia 1894, an Affiliate Fellow of the American Medical Association and member of the House of Delegates from 1930 to 1939, member of the American Public Health Association, past president of the Medical Society of the State of Pennsylvania and the Pennsylvania Public Health Association past president and secretary of the Huntingdon County Medical Society fellow of the American College of Surgeons, member of the advisory health board of the Pennsylvania Department of Health from 1923 to 1931, medical director of Huntingdon County from 1908 to 1925 physician from 1895 to 1908 consulting physician from 1908 to 1923 and vice president of the board of trustees from 1923 to 1931, Pennsylvania Industrial Reformatory, for many years surgeon and trustee of the J C Blair Memorial Hospital, surgeon for several railroads and numerous industrial plants aged 71, died, October 29 in the Friends Hospital Philadelphia, of arteriosclerotic heart disease

William Edward Fairfield, Green Bay, Wis., University of Bishop College Faculty of Medicine, Montreal, Que., Canada, 1887, fellow of the American College of Surgeons, served as a captain in the medical corps of the U S Army during World War I, for many years a member of the hospital board and president of the medical staff of St Mary's Hospital, surgeon to St Vincent's Hospital, with Dr W H Bartran established the Fairfield-Bartran Clinic, aged 80 died, October 18, of epithelioma of the face

Frederick Bryton Little, Norristown Pa., University of Pennsylvania School of Medicine, Philadelphia, 1915, member of the Medical Society of the State of Pennsylvania served in the medical corps of the U S Army during World War I and received citations from the English and Russian governments aged 52, member of the board of directors of the Riverview Hospital, on the staff of the Montgomery Hospital, where he died, October 31, of cerebral hemorrhage

James Craig Strong ⊕ Leadville, Colo., University of Nashville (Tenn.) Medical Department, 1900 Kentucky School of Medicine, Louisville, 1903, member of the American Academy of Ophthalmology and Otolaryngology president and formerly secretary of the Lake County Medical Society, at one time secretary of St Francis (Ark.) Medical Society, on the staff of St Vincent Hospital, aged 64, died, October 14, of coronary thrombosis

William John Jones, Tacoma, Wash., University of Oregon Medical School, Portland, 1915, member of the Washington State Medical Association, fellow of the American College of Surgeons, served during World War I, coroner of King County from 1926 to 1934, formerly member of the staffs of St Luke's, Providence, Swedish and King County hospitals, Seattle, aged 56, died, October 25, at American Lake

Gardner Rich Riddlon ⊕ Seattle, Columbia University College of Physicians and Surgeons, New York, 1925, specialist certified by the American Board of Urology, Inc., member of the American Urological Association, on the staffs of the Providence Hospital and the Firland Sanatorium, aged 43 died suddenly while on a hunting trip just outside of Ellensburg, November 1

James Ross Mossgrave ⊕ Steubenville, Ohio, University of Pennsylvania Department of Medicine, Philadelphia 1897, at one time secretary of the Jefferson County Medical Society formerly served on the board of education, on the staffs of the Ohio Valley and Gill Memorial hospitals, aged 67, died, October 28, of cerebral arteriosclerosis and diabetes mellitus

Charles Given Foote, San Diego, Calif., University of Wooster Medical Department, Cleveland, 1895, member of the American Urological Association, formerly associate professor of genitourinary diseases at the Cleveland College of Physicians and Surgeons, at one time on the staff of the City Hospital, Cleveland, aged 69 died, October 22

William B Linton ⊕ Minneapolis, Jefferson Medical College of Philadelphia, 1886, an Affiliate Fellow of the American Medical Association, formerly on the staff of the Rochester (Minn.) State Hospital, aged 86 died, September 13, in the Eitel Hospital of cerebral hemorrhage with right hemiplegia and carcinoma of the prostate

Thomas Augustine O'Brien, New Haven Conn. Yale University School of Medicine, New Haven 1902, served as a first lieutenant in the medical corps of the U S Army during World War I formerly clinical assistant at his alma mater, served as assistant surgeon at the Hospital of St Raphael, aged 63, died October 24

William Pickens Harbin Sr ⊕ Rome, Ga., Bellevue Hospital Medical College New York, 1897, fellow of the American College of Surgeons, formerly member of the board of trustees of the Shorter College aged 70 co founder and on the attending staff of the Harbin Hospital where he died, November 4

Almon H Lyman, Fillmore N Y, University of Buffalo School of Medicine, 1884 University of Pennsylvania Department of Medicine Philadelphia, 1895 member of the Medical Society of the State of New York medical superintendent of the Genesee Country Memorial Hospital, aged 80, died, October 22

Martha Hayward, Aurora, Ill. Colorado School of Medicine, Boulder 1906 College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1907 at one time superintendent of the Aurora Hospital, aged 74 died, October 30, in the Copley Hospital of cerebral hemorrhage

Ernest Linwood Cheney, Duluth, Minn., Harvard Medical School Boston, 1900, member of the Minnesota State Medical Association, for many years associated with the U S Public

Health Service, aged 65 died, October 30, in St Luke's Hospital of myocardial insufficiency and pulmonary embolism

John Marion McFarling ☉ Shawnee, Okla., University of Oklahoma School of Medicine, Oklahoma City, 1935, formerly secretary of the Pottawatomie County Medical Society, secretary of the staff of the Shawnee Municipal Hospital, aged 39 died suddenly, October 27, of coronary occlusion

Andreas Pederson Lommen, Lanesboro, Minn., University of Minnesota College of Medicine and Surgery, Minneapolis, 1895, served during World War I, aged 75, died, September 16, in the Veterans Administration Facility, Milwaukee, of cerebral thrombosis

John Witt de Vebre ☉ Ronceverte, W Va., University of Maryland School of Medicine, Baltimore, 1886, formerly secretary of the Greenbrier Valley Medical Society, fellow of the American College of Surgeons, aged 80, died, October 28, of coronary thrombosis

Preston David Geiger ☉ Providence, R I. Hahnemann Medical College and Hospital of Philadelphia, 1925, member of the New England Pediatric Society, head of the pediatric department, Homeopathic Hospital, aged 43, died, October 24, of coronary thrombosis

Gamble Morris O'Malley, Weimar, Calif. Long Island College Hospital, Brooklyn 1896, on the staff of the Weimar Joint Sanatorium, aged 67, died October 9 at St Francis Hospital San Francisco, of chronic nephritis with uremia

Homer Alphonzo Gilliam ☉ Mayfield, Ky., University of Louisville (Ky.) Medical Department, 1909, aged 58, one of the founders and president of the Fuller-Gilliam Hospital, where he died, November 4, of coronary occlusion

John C Hoover ☉ Owensboro Ky., College of Physicians and Surgeons of Chicago, 1883, fellow of the American College of Surgeons, on the staff of the Owensboro City Hospital, aged 80 died October 30, of cardiorenal disease

David Jacobs Kutcher, Pattonville Mo. University of Moscow Faculty of Medicine, Russia 1916, resident physician, Jewish Sanatorium, Robertson, aged 56, died suddenly, October 26, of pulmonary embolism

Landon Hayes Gammon, Bristol, Tenn., University of Maryland School of Medicine, Baltimore, 1892 formerly mayor of Bristol, aged 81, died, October 30, of arteriosclerotic heart disease and hypertension

Fergus Joseph McDonough, Brooklyn Long Island College Hospital, Brooklyn, 1899, member of the Medical Society of the State of New York, aged 78, died October 30, of acute cardiac decompensation

Charles Martin Matter ☉ Chicago, Northwestern University Medical School, Chicago, 1898, at one time on the staffs of the Evangelical and Wesley Memorial hospitals, aged 67 died November 7

Edward E Woodside, Marion Ill., Rush Medical College, Chicago, 1905 member of the Illinois State Medical Society, aged 66, died, October 24, in the Herrin (Ill.) Hospital of cerebral hemorrhage

James Henry Frey, Clarksville, Tenn., University of Tennessee Medical Department, Nashville, 1894, member of the medical reserve corps during World War I, aged 72, died, November 4

Johnson Nichols McCartney, Maitland, Fla., Hahnemann Medical College and Hospital, Chicago, 1897, served overseas during World War I, aged 69, died, October 24, of cerebral hemorrhage

Philip Simerman, New York, Long Island College Hospital, Brooklyn 1912, member of the Medical Society of the State of New York, aged 53 died, October 23, of coronary thrombosis

Edward William Wiles, Des Moines Iowa, Detroit College of Medicine, 1911, physician for the Girls Training School, Mitchellville, aged 54, died suddenly, November 3, of coronary thrombosis

Charles E Vance, Middletown Ohio, Starling Medical College, Columbus 1883 aged 84, died October 16, in the Middletown Hospital of extensive carcinoma of the liver and stomach

Lewis K Maxwell, Toledo, Ohio, Homeopathic Hospital College, Cleveland, 1883, a member of the staffs of the Mercy and the Toledo hospitals, aged 85, hanged himself, October 29

Carl Shuey Owen ☉ National City, Calif., Northwestern University Medical School, Chicago, 1904, attending physician and part owner of the Elwyn Hospital, aged 64, died recently

Edward Brandon Newsom, Rockwood, Texas, University of Texas School of Medicine, Galveston, 1897, aged 75, died, October 26, in the John Sealy Hospital, Galveston

Charles A Lumsden, De Witt, Ark., University of Arkansas School of Medicine, Little Rock, 1912, member of the Arkansas Medical Society, aged 64, died, October 27

William Zeller Kumler, Hamilton, Ohio, Homeopathic Hospital College, Cleveland 1885, aged 82 died October 14, in the Fort Hamilton Hospital of cerebral embolism

Harold Bonaventure Fear ☉ Greeland, Pa. Georgetown University School of Medicine, Washington, D C, 1933, aged 35 died, October 22, of carcinoma of the stomach

Elmer Julius Eklund ☉ Norwood, Minn., University of Minnesota College of Medicine and Surgery Minneapolis, 1907, aged 57, died, October 28, of coronary occlusion

W Muldrow Brockinton, Manning, S C. Medical College of the State of South Carolina, Charleston, 1887, aged 76, died, October 16 of a self inflicted gunshot wound

Sallie V Rutledge Johnson, Lancaster, Pa. Woman's Medical College of Pennsylvania, Philadelphia, 1929, aged 44, died, October 29, of poison, self administered

Lee Clanton, Rockford, Wis. Finsworth Medical College, St Joseph, Mo, 1906 aged 67, was found dead in his automobile October 21, of coronary heart disease

Gilman Erastus Baldwin, Jiy N Y. University of Vermont College of Medicine Burlington, 1873, aged 92, died, October 17, of myocardial degeneration

William P Shelly, Albany Gr. Louisville (Ky.) Medical College, 1878 member of the Medical Association of Georgia, aged 86 died October 23 of jaundice

Millie J Heilman, St Louis American Medical College, St Louis 1894, aged 81, died, November 2, at the Lutheran Convalescent Home of pneumonia

Henry Warren Johnson, Mountain Calif. Boston University School of Medicine, 1888 aged 86, died, October 19, of perforated ulcer of the stomach

Leslie Handlin George, Haverhill, Mass., Maryland Medical College, Baltimore 1903, aged 63, died suddenly, October 22 of coronary thrombosis

B Du Bois Buxton, Mount Gilard Ohio, Eclectic Medical Institute, Cincinnati, 1871, aged 93, died, October 29, of arteriosclerosis and prostatitis

Elbridge Tidrick Likes, Des Moines, Iowa Detroit Medical College, 1875 aged 90, died, October 15, in the Mercy Hospital of myocarditis

George Lee Withers, Davidson, N C., North Carolina Medical College, Charlotte, 1914, aged 60, died, October 20, of cardiac disease

William Don Brooks, Jackson, Mich., University of Michigan Homeopathic Medical School, Ann Arbor, 1903, aged 62, died, August 27

M H Roberts, Greenwood, Miss., Memphis (Tenn.) Hospital Medical College, 1901, aged 76, died, October 13, of abscessed liver

David H Pruett, Hurricane Mills Tenn., University of Tennessee Medical Department, Nashville, 1892, aged 73, died, September 12

James G Fickel, Carlisle Pa., Hahnemann Medical College and Hospital of Philadelphia, 1879, aged 89, died, September 13

John William Weed, Thurman Iowa, John A Crighton Medical College, Omaha, 1904, aged 65, died, August 22, in Iowa City

James Hiram Bindley, San Antonio, Texas Cincinnati College of Medicine and Surgery, 1893, aged 71 died, October 31

Walter Perry Thorp, Clearfield, Pa., Baltimore Medical College, 1905, aged 68, died, October 19, of mitral stenosis

DIED WHILE IN MILITARY SERVICE

John David Reid, Ironwood Mich. University of Michigan Medical School, Ann Arbor, 1935 member of the Michigan State Medical Society, first lieutenant in the Army of the United States called to active duty Sept 16, 1942, aged 32, was killed, October 23, when the automobile in which he was driving was struck by a train near Camp McCoy, Wis, where he was stationed

Bureau of Investigation

SOME MISCELLANEOUS MEDICAL FRAUDS

A Variety of Schemes Debarred from the Mails

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of THE JOURNAL. Following are brief abstracts of some fraud orders not dealt with previously.

George Glass—From Fairy Hill Saskatchewan Canada this person advertised that for 50 cents he would send a recipe for Nature's Scientific Method for Crowning Hair and Cure for Baldness. The word "Cure" became "Relief" in the instructions which came with the treatment and which went on to say: "Young persons who have lost their hair after fevers the washing of the head with cold water is helpful. Against the early falling out of the hair without any cause or weakening disease [sic] I recommend the following Hair Pomade: Cold prepared chloroform 4 grams lard 30 grams bitter almond oil 50 drops. Mix everything thoroughly together and take teaspoonful and rub it on the bald spots of the hair every evening." Glass then went on to suggest another natural hair restorative: "Add 1/2 ounce of the oil of mace to 1/4 of a pint of decolorized alcohol pour 1 spoonful or two into a saucer dip a small stiff brush into it and brush the hair smoothly rubbing the tincture well into the roots." Bathing the head in a strong solution of rock salt is said to benefit gray hair in some instances. A good wash for the hair is 1 teaspoonful of ammonia to a quart of warm water." Medical evidence assembled by the United States Post Office showed that baldness is due to many causes both local and systemic such as fever tuberculosis diabetes venereal diseases glandular disorders and chronic debilitating conditions which cause emaciation and anemia that baldness also may be attributable to heredity or senility, and that such local ailments as ringworm seborrhea psoriasis and other scalp troubles may cause temporary or permanent baldness. As to Glass's first named method that of washing the head with cold water allegedly to regrow hair that has fallen out during fevers the Post Office evidence pointed out that the restoration is due to no such treatment as the hair almost invariably reappears with the passing of the fever. Regarding the second named treatment it was shown that the ingredients mentioned are well known to the medical profession as to their effects and limitations. China extract also known as China root China ginger and ginseng root is a stimulant and irritant to the scalp but lard and bitter almond oil have no effect on the skin or scalp except to soften them. Hence such a treatment would be neither scientific nor effective for growing hair. Glass's third method also was shown to be ineffective because though oil of mace and alcohol are scalp stimulants to some extent one should not expect the mixture to produce any results in baldness which is due to many causes and conditions. Altogether Glass's business was declared to be a scheme for obtaining money through the mails by means of false and fraudulent pretenses representations and promises and accordingly it was debarred from the United States mails by a fraud order issued on Jan. 26, 1942 against the name George Glass.

Kimball Laboratories—This Milwaukee concern originally operated at Minneapolis and was founded around 1920 by an H. B. Kimball who ran it until 1929 when he sold it to a John J. McCloskey. The "Laboratories" sold two treatments through the mails one known as Kimball Tablets' (or Rays of Health) and Kim's Rx. 26. According to the advertising the tablets would among other things rid any person of stomach trouble, ulcers, gall bladder affections, dyspepsia, gastritis, acidosis and similar conditions. Kim's Rx. 26 was claimed to dissolve and remove gallstones and to be superior to surgery in doing so besides overcoming liver and bladder disorders including even advanced cases. According to government chemists the Kimball Tablets contained bismuth subnitrate and sodium bicarbonate 10 grains each, magnesium carbonate 7 grains, kaolin 65 grains, calcium carbonate 2.64 grains, papain and diastase of malt 1 grain each and smaller amounts of saccharin, oleoresin of ginger, pancreatin, pepsin and oil of peppermint. The directions were to take one crushed tablet about an hour after meals with water or milk. Although testimonials quoted in the circular matter repeatedly stated that those who have used these tablets have been enabled to eat anything, persons ordering them received in addition various directions as to diet such as to abstain from foods that have disagreed with you heretofore. At the Post Office hearing of this case as a mail order fraud the testimony of medical witnesses who appeared for the government and others representing the Kimball concern (though one of the last named admitted that he was not an expert on gastroenterology) showed that the term "stomach trouble" includes not merely hyperacidity but also ulcers and cancers of the stomach among many other disorders and their symptoms some of which especially cancers and sometimes ulcers require prompt surgery in order to save the patient's life. The testimony further brought out that lay persons suffering from stomach complaints are incapable of determining for themselves the various causes of their conditions and that the product in question, even when taken according to directions and with the recommended accompanying diet would not overcome the wide variety of stomach ailments cited in the Kimball advertising. Accordingly the Post Office found that the sale of this nostrum constituted a fraud on the public as did also the sale of the other Kimball product Kim's Rx. No. 26 which was represented as a cure for liver disorders and gallstones. According to the Post Office it contained 1 grain each of sodium salicylate and calcium carbonate, 1/2 grain each of sodium taurocholate and sodium glycocholate, 1/4 grain each of cascara sagrada extract and phenolphthalein, 1/5 grain of menthol, 1/16 grain

of podophyllin and some certified food color. According to the undisputed testimony of an expert medical witness for the government disorders of the liver include such serious ones as cancer, cirrhosis and tuberculosis of this organ. Kim's Rx. No. 26 was included with Kimball Tablets as causes for the fraud order which was issued Feb. 23, 1942 against the H. B. Kimball Company and its officers and agents at Milwaukee. Still earlier another government agency had taken action against the Kimball outfit. In November 1937 the Federal Trade Commission announced that it had ordered John J. McCloskey of Milwaukee trading as H. B. Kimball, H. B. Kimball Company and Kimball Laboratories to cease representing directly or through the use of testimonials or endorsements or in any other manner that Kimball Tablets constitute an effective remedy or cure for or have any therapeutic value in the treatment of stomach trouble, ulcers of the stomach, constipation, indigestion, dyspepsia and gastritis or that the product will cure or remove the cause of gas pains, intestinal toxic conditions, acidosis, bloating after meals and symptoms of dyspepsia, provided however that the concern was not to be prevented from representing the product as a palliative treatment for temporary relief of such ailments.

L. M. Gross Medicine Company—For many years a person named L. M. Gross at Little Rock, Ark., now reported by the Post Office Department to be an elderly negro, has been putting out a patent medicine under the name G. S. This she represented as a cure for a wide range of disorders including syphilis, malaria, pellagra, rheumatism and stomach, liver and kidney diseases. In no fewer than five instances of record the Food and Drug Administration brought actions against L. M. Gross or the L. M. Gross Medicine Company for making false and fraudulent representations on the labels of G. S., also known as G. S. Remedy. In one instance the concern was fined but the other cases went by default for want of defense and the court ordered that the shipments in question be confiscated. Finally the business was investigated by the Post Office Department. In November 1941 that department served notice on T. M. Gentry, described as manager of the L. M. Gross Medicine Company and grandson of L. M. Gross, to attend a hearing on Dec. 8, 1941 and answer charges of conducting a fraud through the mails. Neither Gentry nor anyone representing him appeared at the hearing. A month later the Post Office notified Gentry by letter of the evidence that the government had presented at the hearing and gave him an opportunity to abandon the enterprise voluntarily and thus avoid further action leading to the issuance of a fraud order against him. Gentry replied that though L. M. Gross would not consent to discontinue the business Gentry himself would promise to cease any efforts to sell the product in question. Gentry was told that his promise was not considered a proper basis for disposing of the charges against the concern and that the prosecution must go forward unless he filed an affidavit by March 1, 1942 agreeing to abandon the scheme but he did not so file. At the hearing of the case a government chemist testified that he had found G. S. to consist essentially of a 92 per cent alcohol solution containing 0.7968 gram of potassium iodide and 0.5322 gram of soluble plant material in each hundred cubic centimeters with mandrake also present. The government's expert medical witness testified that this mixture when taken as directed would have a laxative action and also some diuretic effect due to the potassium iodide. He also discussed the various diseases for which G. S. was advertised and showed that the nostrum would not cure them. On April 9, 1942 the Post Office issued a fraud order which closed the mails to the L. M. Gross Medicine Company and its officers and agents.

Sur Way Electric Hair Brush Company—This Hollywood, Calif. concern originally was known as Sur Way Manufacturing Company and was run by an R. W. Thompson. An investigation convinced the Post Office Department that the representations in the advertising to the effect that the Sur Way Electric Hair Brush would produce a vigorous growth of hair on any bald head immediately eliminate dandruff and put the scalp into a healthy condition were false and fraudulent. Accordingly the Post Office notified Thompson to show cause on Aug. 19, 1940 why a fraud order should not be issued against him and his concern debarring them from the further use of the mails. Instead of attending the hearing Thompson evaded the fraud order by executing an affidavit which provided not only that he would absolutely discontinue the enterprise but that it would not be continued or resumed by any one else either under the original name or a new designation. It was further agreed that should the business be found to be continuing a fraud order should then be issued against any name or names under which it might be operating. On Sept. 4, 1941 Thompson addressed a letter to the Post Office in which he complained that it was an injustice to him that the business of which he had been deprived by the fraud order was now being operated by a Mrs. P. W. Bell who he claimed had purchased it through his bankruptcy. Mrs. Bell apparently in partnership with her husband continued to operate the fraud through the mails assuming the trade styles Sur Way Electric Company, Sur Way Electric Hair Brush Company and Hollywood Electric Hair Brush Company. The Bells in turn were notified by the Post Office to show cause why they should not be debarred from the mails for conducting a fraud. They did not appear at the hearing of the case held on Dec. 1, 1941 but Mrs. Bell sent an answer to the charges claiming that the former owner of the business had assured her at the time that she purchased it that there was no fraud so long as we made refunds. She further declared that because of her inability to obtain materials she had been forced to close the business in the previous December and since then had been keeping open only to do repair work and make refunds. Nevertheless the Post Office found evidence that she had continued to solicit business through the mails. As the scientific testimony which expert medical witnesses for the government at the hearing held on Dec. 1, 1941 showed that though the electric hair brush in question might stimulate the scalp circulation and even produce a fine downy growth it could not restore hair growing power to follicles which are completely atrophied as is the case in most instances

of haldness Accordingly a fraud order was issued on March 3 1942 against the names Sur Way Electric Company Sur Way Electric Hair Brush Company Hollywood Electric Hair Brush Hollywood Electric Hair Brush Company and their officers and agents

The Pandiculator Company—This department of THE JOURNAL April 4 1942 page 1240 contained an article which reported in detail the fraud order which the Post Office Department had issued on Dec 8 1941 against the Pandiculator Company of Cleveland a concern that for over thirty years had been perpetrating on the public a swindle in the form of an alleged spine stretching height increasing mechanism called The Pandiculator The article showed that according to the evidence brought out at the hearing of this case the business was wholly owned by a Cleveland attorney one Henry C Crowell designated as secretary whose name was included in the fraud order and the discussion concluded with the comment Thus passes—it is hoped—a scheme that has swindled the credulous for many years" Hardly was the ink dry however when it was learned that already (April 3) the Post Office had found it necessary to issue an additional fraud order this one against Crowell himself Soon after the original one was issued the Post Office discovered that the swindle was being continued by Crowell under his personal name and that in one circular letter which he was putting out and which was identical in form and content with one used before the first fraud order was issued Crowell had added the postscript Address me at 11432 Mayfield Rd The circular letter was dated Feb 26 1942 The Post Office inspector whose investigation of the activities of the Pandiculator Company had resulted in the fraud order against it now instituted a test correspondence with H C Crowell He wrote Crowell in effect that he had procured one of the circulars of the Pandiculator concern about a year previously but that recently after sending in an order for the device his letter had been returned marked fraud or something and that he had been advised that a letter to H C Crowell probably would receive a reply It did—on the letterhead of Henry C Crowell who wrote Glad to hear from you Who gave you my address? Yes if you will mail me personally \$25 I will see you get a Lanny Model Better make it prompt Since the evidence gathered by the Post Office clearly indicated that Crowell was seeking to evade the terms of the original fraud order against the Pandiculator Company by soliciting remittances for the device by means of the circular letter containing representations substantially similar to the earlier claims a new fraud order was issued on April 3 1942 against the names H C Crowell and Henry C Crowell

Kansas September Report

The Kansas State Board of Medical Registration and Examination reports the written examination for medical licensure held at Kansas City Sept 15 16, 1942 The examination covered 10 subjects and included 100 questions An average of 75 per cent was required to pass Seventeen candidates were examined, all of whom passed Ten physicians were licensed to practice medicine by reciprocity The following schools were represented

School	PASSED	Year Grad	Number Passed
University of Kansas School of Medicine	(1942 13)		13
Tulane University of Louisiana School of Medicine	(1940)		1
Craighead University School of Medicine	(1942)		1
University of Nebraska College of Medicine	(1941)		1
University of Wisconsin Medical School	(1941)		1
School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Northwestern University Medical School	(1912)		Illinois
Louisiana State University School of Medicine	(1936)		Louisiana
University of Minnesota Medical School	(1939)		Michigan
Medical College of Kansas City	(1903)		Missouri
University Medical College of Kansas City	(1896)		Missouri
Washington University School of Medicine	(1918)		Missouri
University of Nebraska College of Medicine	(1941)		Nebraska
New York Homeopathic Medical College and Flower Hospital	(1925)		Delaware
University of Tennessee College of Medicine	(1940)		Tennessee
Vanderbilt University School of Medicine	(1928)		Alabama

Rhode Island September Report

The Rhode Island Board of Examiners in Medicine reports two physicians licensed to practice medicine on endorsement of credentials of the National Board of Medical Examiners on Sept 10, 1942 The following schools were represented

School	LICENSED BY ENDORSEMENT	Year Grad
Harvard Medical School	(1941)	
Fufts College Medical School	(1941)

MEDICOLEGAL ABSTRACTS

Malpractice Negligent Diagnosis as to Location of Bullet—The patient received a bullet wound on the right side of his back just above the hip and was taken to a hospital for treatment. It was then shortly after midnight on a Sunday morning. First aid was administered and at about 8 a. m. the patient was attended by one of the staff surgeons at the hospital. The patient died at 6 35 p. m. that same day. Subsequently the administrator of the patient's estate filed suit for malpractice against the chief roentgenologist of the hospital and the estate of the staff surgeon, who had died before suit was commenced. From a judgment for the plaintiff, defendants appealed to the Supreme Court of Michigan.

The staff surgeon at the time he examined the patient thought that he felt the bullet through the skin on the right side of the patient's abdomen. Later three roentgenograms were taken. The defendant roentgenologist, who neither saw the patient nor took the roentgenograms, testified that from his examination of the films it was his opinion at the time that the bullet was located in the soft structure just below the surface of the skin and to the left of the median line, in the anterior portion of the left side of the abdomen. When the roentgenograms were received in evidence, they showed that the letter R thereon had been scratched over the letter L. The roentgenologist testified that this change was made owing to the fact that the staff physician disagreed with his diagnosis and that the latter's clinical findings led him to believe that there might have been some confusion in the marking of the roentgenograms. The roentgenologist's first report, made the following day, reported the presence of the bullet in the soft structures to the right of the median line. A second report, however dated about three months later, stated that a further study of the roentgenograms showed the presence of a bullet in the soft structures to the left of the median line. The coroner's physician who performed an autopsy testified that the bullet was found in the abdominal cavity in the left quadrant and that the cause of death was an internal hemorrhage. It was his opinion that an operation to check and ultimately stop hemorrhages by suturing the perforations in the intestine "would have a tendency to preserve life," but that, under the usual and ordinary practice of a surgeon of average skill, a patient who is in a state of shock should not be operated on until that condition has subsided. The plaintiff produced an expert witness who testified that the usual and standard practice of ordinary surgeons and physicians in that community was to have immediate surgical intervention, that an operation is the only thing that stops the hemorrhage and that by stopping the hemorrhage one has a chance to save a person's life. The probability was, he added, that the life of the patient could have been saved by an immediate operation, when the patient was in fairly good condition.

The defendants first contended that the trial court erred in admitting the testimony of the plaintiff's expert because he was only a medical student at the time the patient was shot. The court held that the testimony of such witness was admissible because his study had resulted in the formation of a definite opinion and that he was entitled to express that opinion the weight to be given to his testimony being a matter for the jury. The defendants also contended that it was error to admit the patient's hospital records in evidence since such records were privileged and that the privilege could be waived only by the patient. With this contention the court disagreed, holding that the administrator or executor of the estate of a patient may waive the privilege.

From the autopsy and subsequent study of the roentgenograms, said the court, it was clear that the staff surgeon misapprehended the course which the bullet had taken. If the bullet had in fact lodged on the right side, the wound would have been superficial. Whether or not the surgeon would have operated had he known the true location of the bullet and

whether or not an operation would have saved the patient's life were disputed questions of fact. The jury could have inferred that the staff surgeon relied on his manual examination in which he incorrectly thought that he felt the bullet on the right side, and that he paid little heed to the roentgenograms. Refusal to give them due consideration could be regarded as negligent diagnosis of the serious injury. The roentgenologist, the court continued, testified that a merely casual examination of the roentgenograms had been made and that he found the bullet over the left side when he looked at them carefully. There was expert testimony that the bullet showed plainly on the roentgenograms and that an expert roentgenologist could tell which side of the body was the right or left without resort to any markings on the films. That the defendant roentgenologist did not make a careful study of the roentgenograms was admitted by his own testimony. The jury could infer that if the defendant roentgenologist had studied them more carefully he would not so readily have concluded that there had been some confusion in their marking and would not have had the R scratched over the L. His unconsidered acquiescence with the staff surgeon as to the location of the bullet could be found to have prevented further diagnosis by both of the physicians. Thus the negligence of both resulted in an inaccurate diagnosis of the course taken by the bullet.

Since the medical experts agreed that the deceased was almost certain to die unless an operation were performed, the jury could properly infer that the staff surgeon would have operated if he had known the true position of the bullet. The negligent diagnosis then was the proximate cause of the failure to operate. There was testimony that an operation would probably have saved the patient's life. Therefore the negligent diagnosis could be said to have been the proximate cause of the death. Other contentions of the defendants were also overruled and the judgment for the plaintiff was affirmed.—*Harvey v Silber, 2 N W (2d) 483 (Mich., 1942)*

Workmen's Compensation Acts Disability Resulting from Mental Shock—The claimant, a woman, was employed as an elevator operator. A passenger was caught between the floor of her elevator and the second floor of the building and killed, and the claimant was lodged in the elevator with the dying man for some thirty minutes before the doors were broken in and his body removed. In a subsequent proceeding under the workmen's compensation act, the evidence showed that the claimant suffered so great a shock to her nervous system that her recollection was hazy as to what happened, that she was in a state of extreme excitement when she was removed from the elevator and had lost control of her emotions, that her heart beat was rapid and her blood pressure increased that it was necessary for her to remain in a hospital for several days thereafter, that she was still under medical care at the time of the hearing and that further hospitalization was to be desired. The claimant suffered no physical injury to her person as the result of the accident but did suffer pains in the head and back and she was unable to perform the work of an elevator operator or similar work. She was awarded compensation and the employer appealed to the Supreme Court of Nebraska.

The workmen's compensation act defines an accident as "an unexpected or unforeseen event happening suddenly and violently and producing at the time objective symptoms of an injury. The term 'injury' and 'personal injuries' shall mean only violence to the physical structure of the body." That there was an unexpected or unforeseen event happening suddenly and violently was clear to the court. The evidence showed that the plaintiff was irrational and hysterical after the accident that her blood pressure was considerably higher and that her pulse was more rapid. Medical experts testified that when she was examined, the pupils of her eyes were dilated her posture was abnormal and she had tremors and an inability to walk in her usual manner. These were objective symptoms of injury. Was there violence to the physical structure of the body? Can it be said that disabling shock and nervousness when unaccompanied by an impairment of the physical structure of the body is compensable?

The act requires not only that there be an accident attended by objective symptoms arising out of and in the course of the

employment but that the accident must be accompanied by violence to the physical structure of the body. The language indicated to the court a clear distinction between physical and bodily injury on the one hand and mental nervous and psychiatric injury unaccompanied by violence to the physical structure of the body on the other. The plain import of the words used, as construed by the court, eliminated from the operation of the act disabilities resulting from mental disturbances, nervousness and psychiatric ailments when violence to the physical structure of the body cannot be established. And since the claimant suffered no damage to the physical structure of her body she was not entitled to an award of compensation. Accordingly the award in favor of the claimant was reversed and the preceding dismissed.

A dissenting justice questioned the conclusion reached by the court. In his opinion, the lawmakers, by the use of the term "violence to the physical structure of the body," meant an animate body with a directing brain containing blood, sensitive nerves, fibers and convolutions. The brain, this justice pointed out, is a part of the physical structure of the body and without it there could be no performance of an employee's duties. Accidental violence to the brain and resulting disability may be difficult to prove but in this instance the claimant was rational before the accident and irrational afterward. Her blood pressure was higher and her pulse more rapid. The pupils of her eyes were dilated and her posture abnormal. She had tremors and was unable to walk in her usual manner. These results of the accident, in the view of this justice, presented evidence of "violence to the physical structure of the body" within the meaning of the workmen's compensation act—*Behrle v O F Neal Co*, 4 N W (2d) 741 (Neb. 1942).

Hospitals Liability for Negligence of Hospital Nurse Assisting Physician During Operation—The patient underwent an appendectomy in the defendant hospital being operated on by her own physician. Four hospital nurses assisted in the operation during the course of which the physician called for some warm water with which he intended to irrigate the wound. The water was brought by one of the nurses and was poured in the wound, and because it was too hot the patient was burned. The patient sued the physician and the hospital for damages and obtained a settlement from the physician's insurance company. The hospital refused to participate in the settlement the physician assigned all his rights to the insurance company and in this case the company sought to compel the hospital to contribute its share of the settlement amount on the theory that the nurse or nurses were also negligent and that the hospital was jointly liable with the physician as their employer. From a judgment for the defendant notwithstanding a verdict for the plaintiff, the plaintiff appealed to the Supreme Court of Minnesota.

The sole question determined by the court was whether a hospital can be held liable for the acts of its nurses while they are assisting a physician during an operation. In Minnesota a hospital, private or charitable, is liable to a patient for the torts of its employees under the doctrine of respondeat superior. It follows logically that a physician is also liable, on the same theory, for the negligence of a nurse in his employ. The crux of the case, then, was whether the nurses at the time of the alleged negligence were the employees of the physician or of the hospital. Concededly, they were in the general employ and pay of the hospital and assigned by it to assist in the operation. However, the acts complained of occurred during the operation, were ordered and checked by the operating surgeon and were of such a nature that, according to the surgeon's own testimony, the nurses while performing them were under his absolute control. The court after citing with approval the general rule that "Where a servant has two masters, a general and a special one, the latter, if having the power of direction or control, is the one responsible for the servant's negligence," pointed out that the desirability of the rule was obvious. The patient is completely at the mercy of the surgeon and relies on him to see that all the acts relative to the operation are performed in a careful manner. It is the surgeon's duty to guard against any and all avoidable acts that may result in injury to his patient.

The insurance company contended, however, that even though the physician was responsible for the nurses' acts, the hospital was also liable as "joint master." But, said the court, when the general employer assigns his servant to duty for another and surrenders to the other direction and control in relation to the work to be done, the servant becomes the servant of such other person as far as his services relate to the work so controlled and directed. His general employer is no longer liable for the servant's torts committed in the directed and controlled work. In the operating room the surgeon must be master. He cannot tolerate any other voice in the control of his assistants. In the case at bar, the evidence was clear that the physician had exclusive control over the acts in question, and the court therefore held that the hospital could not be said to have been a "joint master" or "co-master," even though the nurses were in its general employ and paid by it. Accordingly the judgment in favor of the defendant hospital was affirmed—*St Paul Mercury Indemnity Co v St Joseph's Hospital*, 1 N W (2d) 637 (Minn. 1942).

Workmen's Compensation Acts Right of Employer to Require Employee to Submit to Roentgen Examination with Use of Injection of Iodized Poppy Seed Oil—In an action for an award under the Louisiana workmen's compensation act, the defendant employer argued, among other things, that a judgment for the plaintiff employee was erroneous because the trial court had refused to require the plaintiff to submit to a roentgen examination with the use of an injection of iodized poppy seed oil and also had refused to permit the defendant's witness to test in court the reflexes of the plaintiff. The defendant's appeal was to the United States circuit court of appeals, fifth circuit.

The court held that the matter of the achilles reflex test is theoretical and was a harmless indeed almost frivolous error. As to the iodized oil test, the court said that, while an employee must accept simple and harmless treatment the judge, when there is a conflict of opinion among medical experts as to its effect or its danger, has a discretion to order or to refuse to order it. There was positive evidence that the injection of iodized oil might cause serious damage and furthermore that after it was undergone, the conclusions drawn from it were largely negative. Without undertaking to determine whether under other circumstances and other proof an examination with the aid of the iodized oil injection might be properly requested, the court concluded that under the circumstances of this case the trial judge was well within his discretion in refusing to order the plaintiff to submit to the examination. The judgment in favor of the plaintiff was affirmed—*Sullivan, Long & Huggerty Inc v Washington*, 125 F (2d) 166 (1942).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Cerebral Reactions and Mapharsen Treatment of Syphilis—Thomas and his associates treated 764 cases of early syphilis with massive mapharsen therapy. The drug was given in divided doses by syringe, mapharsen alone to 280 patients and mapharsen combined with fever induced by typhoid vaccines to 484. The chief hazard of such treatment is reactions involving the cerebrospinal axis, the only significant laboratory observation of which is increased protein in the spinal fluid. Among the 764 patients treated 16, 2.09 per cent, showed changes indicative of irritation of the central nervous system. Only 8 of the 16 showed clinical signs, severe headaches, unusual complaints or rises in temperature, other than the Herxheimer reaction frequently encountered on the first day of treatment, are indications for examining the spinal fluid. There were no qualitative or consistent quantitative differences in the spinal fluid of those with and of those without clinical signs of encephalitis. Possibly the pathologic process in the symptomless group was confined to silent areas of the cerebrospinal axis, but it is more probable that the spinal fluid changes are not an accurate index of the amount of damage caused by a lowered resistance to arsenic. The combination of fever and mapharsen was originally adopted in the hope of avoiding cerebral reactions, but this hope was not fulfilled as their incidence remained much the same. However, the clinical signs of reactions in the group having fever were milder than those given mapharsen alone. This is probably best explained by the lower dose of mapharsen necessary with fever. No deleterious sequelae have been observed in the 14 who survived. The reactions appeared to vary as to time of onset in relation to treatment and duration of symptoms. In the main they are vascular in type and the functional damage to cells is out of proportion to the structural changes found. The changes in 1 of the fatal cases were attributed to acute syphilitic meningoencephalitis. Erythema of the ninth day was associated in 4 of the patients, this suggests

that there may be a common mechanism underlying these two reactions, but one may occur without the other. Dosage played a more significant role in arsenical encephalitis than is true of the erythema.

Thiamine Hydrochloride in Tabetic Lightning Pains—Cochems and Kemp tried the intravenous use of thiamine hydrochloride for the relief of the lightning pains of 26 patients with tabetic neurosyphilis. The largest amount received by any patient was 3,190 mg in sixty-three doses and the smallest was 20 mg in two doses, the average was 1,098 mg in eighteen doses. No final relief was obtained by 17, partial, possibly permanent, relief by 4 and complete, possibly permanent, relief by 5. The 9 who reported relief have been observed for an average of only seven weeks after subsidence or disappearance of their pain. Six of the 9 have lapsed from observation and the 3 remaining patients have continued regular clinic attendance, but they have been observed for only two weeks, three weeks and six months, respectively, and their relief has apparently been maintained.

Sensitivity and Specificity of Kahn Reaction—Green and Forster used the Kahn verification technique on the serums of 119 syphilitic and 127 nonsyphilitic persons. The tests were made at both 37 and 45 C. Of the 119 syphilitic serums 85 of which gave positive reactions in the verification test, 44 gave greater reactions at 45 C, 23 reacted equally at the two temperatures, 18 gave slightly stronger reactions at 37 C and 34 gave no reaction. The corresponding figures for the 127 nonsyphilitic serums were 1 (doubtful), 0, 0 and 126. In general however, reactions at 45 C were more sensitive than at 37 C by two to four reading units. There were 16 syphilitic serums negative with the standard Kahn test which gave verification reactions of a syphilitic type at 37 and 45 C. To determine the limit of maximal sensitivity of the syphilitic reaction 63 syphilitic serums were tested simultaneously at 37, 45, 50 and 56 C and at 1 C as a control. More serums showed a maximal reaction at 45 C than at the other temperatures, it dropped off slightly but progressively at 50 and 56 C. Apparently the usefulness of the verification reaction lies no less in the diagnosis of syphilis than in the recognition of falsely positive reactions.

Continuous Spinal Anesthesia—Apgar discusses difficulties encountered while administering continuous spinal anesthesia to 422 patients. The chief difficulties have been in maintaining an adequate blood pressure and in controlling pain and retching associated with traction in the upper part of the abdomen. In 60 per cent the state of the circulation was unsatisfactory (a low systolic pressure, a small pulse pressure and usually a slow pulse rate) at some time during the operation. The usual precipitating causes for the drop in pressure were too much procaine at one time, traction on abdominal viscera and change of position during anesthesia. Ephedrine in divided doses raised the pressure in all but 25 in whom it was tried. In these 0.2 cc of a 1:1,000 solution of epinephrine fifteen to twenty minutes after ephedrine usually produced a moderate and sustained increase. The next unsolved problem was epigastric or substernal pain, with retching vomiting or hiccups during operations on the upper part of the abdomen. Morphine and scopolamine proved satisfactory for controlling these reactions. A few patients became uncooperative, restless and talkative from the preoperative medication but were con-

trolled by small amounts of 25 per cent pentothal sodium. Some technical difficulties arose, in 5 elderly arthritic patients the needle could not be introduced, in 3 no anesthesia was obtained, in 1 the needle became displaced while the patient was being moved from the supine to the lithotomy position and in 1 after two hours of satisfactory anesthesia the needle became plugged with a small foreign body. This high incidence of difficulties was due in part to the frequent change of residents. The best feature of the method is the absence of severe respiratory depression during operation. For operations on the upper part of the abdomen endotracheal anesthesia with either cyclopropane or ether is more controllable and protects the patient better from reflex disturbance, but the method has a definite place in operations on the lower part of the abdomen, in prolonged operations on the extremities or in the open reduction of comminuted fractures. For any operation likely to involve unusual blood loss, inhalational methods are better.

Intranasal Application of Sulfonamide Powder—Brown

applied a sulfonamide powder intranasally to 5 patients with chronic purulent sinusitis who would have been advised to have a radical operation on the affected sinuses had it not been for the improvement that followed this treatment. All 5 patients have been dismissed as well. Under local anesthesia a submucous resection was done unless the nasal septum was deviated sharply away from the infected side. Half of the anterior middle turbinate was removed. The natural ostium of the antrum was enlarged with a sphenoid punch forceps to at least three times its normal size. The nasofrontal duct was located, and the anterior ethmoid cells around this were removed. A rasp was introduced into the nasofrontal duct and the duct was enlarged so that a number 3 eustachian catheter could be passed into the frontal sinus with ease. If the posterior cells or the sphenoid sinus were infected, more ethmoid cells were removed. The frontal and maxillary sinuses were washed with saline solution and then followed by injection of air. The eustachian catheter was passed into the frontal sinus through the enlarged opening, a column of air from the wall pressure or small motor compressor under extremely low pressure was blown through the loosely fitting catheter, and when it was ascertained that there was no obstruction a common powder blower, half filled with a sulfonamide powder, was inserted into the dilated end of the eustachian catheter, the air pressure was attached to the powder blower and sufficient powder was blown into the sinus to cause some to come into the nose from the sinus. This procedure was repeated in the maxillary sinus through the enlarged natural ostium. A small amount of powder was sprayed directly from the powder blower into the anterior ethmoid region. Light nasal packing of plain gauze was used only when a submucous resection was done to hold the septal flaps together, and it was removed in about eighteen hours. If the patient complains of severe pain when the rasp is introduced, a general anesthetic is given. Patients usually went home on the third day, when the sinuses were again insufflated. After this, for four to eight

weeks, insufflation was carried out twice a week at the office. For the procedure in the office the nose was prepared by spraying it with a 1 per cent aqueous solution of cocaine hydrochloride after the sinuses were washed with saline solution.

Prevention of Postoperative Peritonitis—Dixon and his associates compare data on 639 colon operations performed on 480 patients. Preceding 258 of them the vaccine was administered peritoneally and in 381 it was not administered. There were 18 hospital deaths among the first and 39 among the second group of operations, the respective figures for peritonitis were 10 and 25. A further comparison, made according to type of operation and the operating surgeon, showed about the same consistent advantage for the group that had received the vaccine as for the overall average results. Study revealed that the postvaccinal rise of temperature was an indication of immunity to postoperative peritonitis. Among patients whose postvaccinal temperature did not rise above 99.6 F there was a definite reduction in the postoperative mortality rate as compared with patients whose postvaccinal temperature exceeded 99.6 F, indicating that the patient in whom the postvaccinal temperature did not rise above 99.6 F was relatively immune to postoperative peritonitis. Study of patients who received two vaccinations showed that

the postoperative mortality rate was lower in the group in whom the rise of temperature after the second vaccination was lower than after the first than in the group in whom the postvaccinal rise of temperature after the second vaccination was higher than that after the first. The results suggest that the efficiency of intraperitoneal injection of vaccine conferring immunity against postoperative peritonitis could be increased if prior to operation more than one vaccination was utilized and if one was guided by the postvaccinal rise of temperature following the first vaccination. A suggested plan includes multiple intraperitoneal injections six to eight days preoperatively. The intraperitoneal vaccine consisted of a sterile suspension of *Escherichia coli* and green producing streptococci. Intraperitoneal injections of solution of sodium chloride as practiced by Morton were also effective against postoperative peritonitis.

Results Following Ligation of Internal Carotid Artery—Dandy states that with care in the interpretation of the preoperative tests of the adequacy of collateral circulation in the brain and with proper choice of the method of ligation of the internal or common carotid artery the two causes of death and disability, cerebral anemia and cerebral thrombosis and embolism, can now be largely eliminated. In his series of 88 cases all but 3 were ligations of the internal carotid. In the 3 exceptions in addition to the common carotid, the external carotid was tied, so that the equivalent of ligation of the internal carotid resulted. All but 3 were total ligations for verified arterial or arteriovenous aneurysm of the brain or cerebral tumor. There were 4 immediate cerebral complications, 1 late cerebral complication and 4 deaths. The death of 1 patient was in no way connected with the operation, as the patient was dying at the time of the ligation. Another death was due to rupture of an intracranial aneurysm which was known to have broken when the operation was performed. If these 2 cases are eliminated the mortality rate is 2.25 per cent. With greater care in applying an intracranial silver clip another death might have been prevented, and if a band of fascia had been interposed between the internal carotid and the silk ligature the late appearing hemiplegia and subsequent death of the fourth patient might also have been avoided. From the complications it appears that partial ligations are the most hazardous. The Matas test (compression of the internal carotid for ten minutes to determine whether or not cerebral functions are disturbed) was responsible for the low mortality and few cerebral complications. Many patients, regardless of age, will not tolerate total ligation. Partial closure will quickly establish cerebral collateral circulation, and complete closure can be safely concluded in about a week. By this means the reduced flow of blood through the internal carotid is adequate for the cerebral blood supply but at the same time the demand is made for the anterior and posterior communicating arteries to supply the created deficit. There was no disturbance when total ligation followed preliminary partial closure. Without the Matas test most if not all of these patients would have died or been badly crippled from the effects of inadequate cerebral circulation if total occlusion had been done first. The danger in partial occlusion is in obliterating the lumen too far. If cerebral signs develop during the succeeding six or eight hours the band can be removed, and at times the cerebral circulation will be restored. For total ligation an interposed fascial band is probably the best assurance against thrombosis and the resulting late cerebral complications.

Prophylaxis of Postoperative Thrombosis and Embolism—Butsch and Stewart determined the value of the practical use of the anticoagulant dicoumarin, which requires twenty-four to forty-eight hours to produce its effect, in 23 males undergoing inguinal herniorrhaphy to prolong the clotting time of the blood in the prophylaxis and treatment of thromboembolic disease. As the operative procedure was limited to the abdominal wall, any postoperative hemorrhagic phenomena could be readily discovered and corrected. Eighteen were operated on forty-eight hours after dicoumarin was begun orally and 5 still later. A dose of 0.32 Gm of the agent was given by mouth in the morning two days and one day before operation. In every instance the incised tissue appeared normal, as was the healing process, the amount of blood oozing and hemostasis.

Twenty one wounds healed primarily, in 2 hematomas developed which required one aspiration for subsequent complete healing. The study demonstrates that herniorrhaphy can be performed with reasonable safety on patients with impairment in clotting produced by dicoumarin. Apparently enough thromboplastic substance is liberated in the incised wound to promote reasonably satisfactory hemostasis after the wound is sutured. The compound should not be given to patients with ulcerating or granulating areas because of the danger of hemorrhage from these areas.

Pernicious Anemia and Carcinoma of Stomach—From 1917 to 1939 inclusive, according to Doehring and Eusterman 40 patients with both pernicious anemia and carcinoma of the stomach were examined at the Mayo Clinic. In 26 the diagnosis of pernicious anemia preceded that of gastric carcinoma and in 12 it was simultaneous. During the five years 1936 to 1939 approximately 1,014 patients with pernicious anemia were treated at the clinic and 17 of these had carcinoma of the stomach also. This incidence of 1.7 per cent seems slightly greater than the calculated incidence for the adult general population. The average age at which symptoms referable to pernicious anemia occurred was 54.5 years while that for the symptoms of carcinoma was 63.2 years. Although present evidence is insufficient to prove a direct relation between the two diseases, there are grounds for suspecting that persons with pernicious anemia are more likely to have gastric carcinoma than normal persons.

Hypersensitivity in Periarteritis Nodosa—Rich states that at Johns Hopkins Hospital a case of serum sickness rarely came to necropsy before the advent of sulfonamide therapy. Since its introduction necropsies on patients with serum sickness or on those who had had serum sickness shortly before death have been more frequent, as even in ultimately fatal cases the sulfonamides, used in conjunction with antiserum may prolong life sufficiently to permit serum sickness to develop before death. Within nine months there were 4 cases with manifestations of serum sickness developing during the terminal illness. Because of the infrequency of necropsies on patients with serum sickness the first case was examined with particular interest and fresh lesions of periarteritis nodosa were encountered. The subsequent cases were studied carefully and again widespread, fresh lesions of periarteritis nodosa were found. In a fifth patient, who had received antiserum for pneumonia, serum sickness developed. A biopsy of a small piece of biceps muscle revealed definite periarterial inflammatory infiltration with polymorphonuclear and mononuclear cells. This patient was discharged in three months with hypertension and a slight persistent diminution in renal function. All 5 patients had been treated with foreign serum as well as sulfonamides, and 1 additional case indicated that sulfathiazole may, under certain conditions, produce lesions of periarteritis nodosa. This patient had carcinoma of the pancreas. Operation was limited to exploratory laparotomy and the patient was given repeated doses of sulfathiazole orally and intravenously as a prophylactic measure against aspiration pneumonia. Death occurred in a week. At necropsy hyaline necrosis and perivascular infiltration with mononuclear and polymorphonuclear cells characteristic of periarteritis nodosa were revealed. There were

widespread focal parenchymal lesions in the viscera (necrosis and infiltration with inflammatory cells) Only 1 of the 5 patients treated with serum had received sulfathiazole before the rash of serum sickness appeared, and the sixth received no sulfonamide drug That serum sickness in the absence of sulfonamide therapy may be accompanied by lesions of periarteritis nodosa is suggested by the necropsy of only 1 patient who had had serum sickness shortly before death and who was treated before the sulfonamide era Therefore 4 of the 5 patients had received sulfonamides, but in at least 2 of them evidence indicates that the hypersensitive reaction was serum sickness and not drug hypersensitivity None of the patients had symptoms suggesting periarteritis nodosa prior to their terminal acute illness for which the serum and/or sulfonamide was administered This study and other pertinent evidence indicate that these vascular lesions can be a manifestation of anaphylactic hypersensitivity and suggest that the inciting antigen be searched for

Vitamin B in Emesis and Hyperemesis Gravidarum—Hart and Torpin treated nausea and vomiting of 37 women in early and late pregnancy with a product containing 5 mg of thiamine hydrochloride, 5 mg of riboflavin, 25 mg of nicotinamide, 6 mg of pyridoxine and 25 mg of pantothenic acid to the tablet. The dose for 8 was one tablet three times a day, 7 were relieved in a week and 1 felt better but continued to vomit occasionally until delivery Nicotinic acid in doses varying from 150 to 200 mg a day was given 29, of these 8 obtained no relief, 8 were completely relieved, 9 were partially

relieved and 4 were not followed sufficiently Those who received partial relief stated that the vomiting had stopped but that some degree of nausea persisted If these patients were not given the vitamin B tablets the vomiting would probably recur in about three weeks, despite the nicotinic acid The vitamin B tablets were administered to 5 and their nausea completely disappeared When relief was obtained the average patient usually noticed it about two days after starting medication Most likely many of the patients had subclinical pellagra, as the diets of many were known to be borderline. Others probably had exhausted their vitamin B by vomiting The metabolic increase and dietary perversions accompanying pregnancy probably served as precipitating factors

Treatment of Simmonds' Disease—Williams and Whittenberger treated 5 unselected cases of Simmonds' diseases with thyroid extract, desoxycorticosterone acetate, sodium chloride and testosterone. The patients had had their disease for five to twenty years None of the patients had had any sexual activity for several years The 4 women had had amenorrhea for a long time but none had experienced menopausal reactions All had clearcut symptoms of myxedema. Contrary to the usually expected characteristic cachexia, not 1 of the patients was cachectic. There was little, if any, axillary or pubic hair, and essentially no hair on the trunk. There was no atrophy of the breasts Most of the difficulty was encountered in estimating the number of pellets of desoxycorticosterone acetate which was necessary At the time of discharge the number of 125 mg pellets of desoxycorticosterone acetate used varied from one to six One patient was discharged with instructions for taking 3 Gm of salt daily, another was taking 8 Gm daily, while none was prescribed for the other 3 The initial dose of thyroid was $\frac{1}{2}$ grain (0.032 Gm), and this was increased until, by clinical observation and according to the basal metabolic rate, there was no evidence of thyroid insufficiency The ultimate dose varied from $\frac{1}{2}$ to 2 grains (0.032 to 0.13 Gm) The more the thyroid was increased, the more the desoxycorticosterone acetate had to be increased The use of enough testosterone in women to secure an increase in strength, energy and general well being without masculinization was usually one or two pellets (150 mg each) The dose for the male was governed by these general reactions and by the amount of sexual stimulation Three pellets were required. Each patient took small amounts of food between meals and at bedtime to distribute the supply of carbohydrates evenly over the twenty-four hours, thereby preventing hypoglycemic reactions In all the blood pressure, basal metabolic rate and serum sodium returned to and have remained normal The myxedematous manifestations have disappeared. Their mental state has changed from a dull, irritable and depressed level to an alert and cheerful one None of the symptoms of adrenal

insufficiency have reappeared. Of the 3 patients with normocytic and normochromic anemia who had not responded to iron or liver, the anemia has disappeared in 2. In no case was there enough overgrowth of hair to cause concern.

Hormone Preparations and Blood Vascular Disorders—Walker reports the results of treating 82 persons with androgenic and estrogenic substances. Fifty-six patients had essential hypertension, 12 angina pectoris and 14 organic peripheral vascular disease. In the entire group of hypertensive patients, treatment with gonadotropic substances has resulted in a more pronounced and more prolonged lowering of the blood pressure than was usually obtained by other medical methods. Moreover, the effect of these substances on occlusive peripheral vascular disease and angina pectoris is further indicative of their pronounced vasodilating action. Subjective improvement was more evident than is usually observed following other therapeutic methods. The data favor the concept of a direct vasodilating action of the hormone preparations although not in keeping with the fact that the blood pressure is occasionally elevated in hypotensive persons as a result of gonadotropic therapy. While the gross mechanism by which the hormone preparations favorably influence vasospastic phenomena is obviously vasodilatation, the finer mechanism may be the establishment of an endocrine balance.

Myasthenia Gravis, Effect of Thymectomy—The state of neuromuscular transmission and the effect of prostigmine methylsulfate and acetylcholine injected into the brachial artery of 5 patients with severe myasthenia gravis five months after total thymectomy has been studied by Harvey and his associates. The partial block in neuromuscular transmission and the abnormal reactions to the intra-arterial injection of prostigmine methylsulfate which existed preoperatively were altered profoundly. The results indicate that in myasthenia gravis the thymus influences greatly the function of the motor nerves and the striated muscles which they innervate. The data furnish objective evidence of the normal physiologic function of the thymus. In addition to changes in the physiologic and pharmacologic patterns of neuromuscular function which followed thymectomy, an extraordinary clinical improvement ensued in 3 patients concomitantly with the reversion of neuromuscular function toward normal. Local fasciculations developed following the intra-arterial injection of prostigmine methylsulfate, the muscle action potential, in response to a maximal motor nerve stimulus, increased enormously, indicating that

more muscle fibers were excited, the characteristic depression of neuromuscular function following activity at the junction was eliminated or greatly diminished, the response to a single stimulus after the injection of prostigmine methylsulfate became repetitive as in the normal subject, in 2 patients a normal depression of neuromuscular function developed after the intra-arterial injection of prostigmine methylsulfate and in 1 the muscle threshold rose after injection of acetylcholine into the brachial artery. The evidence indicates that in certain individuals the thymus plays an important role in the pathogenesis of myasthenia gravis. The changes after thymectomy indicate an increase in the amount of transmitter substance available at the neuromuscular junction.

Therapy of Experimental Streptococcal Erythema—Tyrothricin, a bactericidal substance derived from a strain of group A hemolytic streptococcus obtained from the blood stream of a patient with erysipelas who subsequently died and the virulence of which increased for rabbits by frequent animal passage, was used by Rammelkamp in the treatment of streptococcal erythema in rabbits. The experiments demonstrated that the pleural cavity of rabbits could be sterilized by the injection of 3 to 40 mg of the bactericidal substance. The tyrothricin was administered as a single injection at the time of infection or up to eighteen hours later. Occasionally an animal died if treatment was delayed. Death of these animals was due to extension of the infection to the pericardium and the opposite pleural cavity before tyrothricin therapy was instituted, since the treated cavity was sterile at postmortem examination. Staphylococcal infections of the pleural cavity were somewhat more resistant to this therapy. The tyrothricin produced certain local toxic effects which would be undesirable if the substance was to be employed for treating human infec-

tion Perhaps many of the toxic reactions may be avoided by using a more purified extract The two active crystalline substances gramicidin and tyrocidine separated from tyrothricin may be less toxic Gramicidin, which is more bactericidal than tyrocidine or tyrothricin, comprises less than half the total weight of the crude substance tyrothricin Its toxic effects have not been thoroughly investigated, but it is safe to say that it is less toxic for erythrocytes, leukocytes and tissue in general than tyrocidine or tyrothricin The results suggest that gramicidin may prove useful in treating empyema

Benzene Poisoning in Industry—The national defense program, altering industry to suit its needs, Wilson states, has placed increasing burdens on the industrial physician, especially in the rubber industry with its increased use of benzene and its physical hazards Poisoning from it is due to absorption by the respiratory, alimentary or cutaneous route The statistics of a factory in the rubber industry that has been using benzene in small quantities for years show that, with the advent of large war orders and the increasing use of synthetic rubber, workers came to the company hospital with complaints of malaise, nausea and vomiting, and a few with bleeding Immediate blood counts were done on the 1,104 people using benzene, in 83, or 75 per cent, there were mild blood changes and symptoms of slight absorption of benzene fumes Twenty-five, or 22 per cent, showed severe blood changes with symptoms of severe benzene intoxication, 9 of these 25 were hospitalized and received from two to fifty blood transfusions Three of the 9 died This low mortality incidence was believed to be due to the extreme amount of treatment received, consisting of multiple whole blood and direct bone marrow transfusions, and liver, iron, calcium, phosphorus, yellow bone marrow and multiple vitamin therapy Prophylactic measures include adequate ventilation and constant medical supervision, that is, frequent blood examinations Frequent air samples should be tested with a combustible gas indicator and ventilation introduced to keep the concentration of benzene in the air below one hundred parts per million No one should be permitted to work in a benzene department with a leukocyte count below 5,000 or one above 13,000 After ten days of employment the employee should be given a urinary sulfate test, if the ratio is below 50 a tendency to absorption exists and the employee should be removed from the benzene department Also a drop of 25 per cent in any blood component is sufficient reason for removal An ideal arrangement would be repeated blood checks on exposed employees

Blood Pattern and Malignant Disease—Bolen used the Goldberger sedimentation test on the blood of every patient to see whether it would afford material aid in diagnosis, prognosis and therapy The most interesting phenomenon was the distinctive pattern of the blood obtained from patients with cancer The pattern characteristic of blood from normal subjects and patients with ulcer, inflammatory disease and the like was devoid of meshwork There was no breaking up of the fibrin,

the blood was more compact In the central part of each drop of blood there was a dark agglutinated mass Invariably the pattern formed by blood from cancerous patients was what he describes as the "dotted curtain" type Peripheral rings were absent and no agglutinated mass was seen in the center The blood was broken down into "dots" Under the microscope the cancerous blood showed numerous three cornered triasteroid spicules scattered throughout These spicules or rays were not found in any other condition in such abundance In acute rheumatic fever, rheumatoid arthritis, active tuberculosis, pregnancy, pernicious anemia and coronary disease a positive pattern was also obtained, but in all of these the clinical observations differentiated the condition from cancer and furthermore the positive reaction gradually changed to negative as proper treatment was instituted This same transition from a positive to a negative blood pattern occurred when 'cures' were obtained in cancer patients, either by total surgical extirpation, radium implantation or high voltage roentgen therapy Of the 132 patients that the author has encountered since 1939 and noted the type of blood pattern, he noticed a positive reaction in only two conditions diverticulitis and endometriosis The margin of error was only 15 per cent Slides of 140 patients with proved cancer show one hundred and twenty eight to be positive and twelve to be negative The erythrocyte count, the leukocyte count and the hemoglobin appeared to have no relationship to the cancerous blood pattern on the slide The test is offered as an adjunct to be evaluated along with clinical and laboratory observations Sometimes this cancer pattern can be the sole evidence of the presence of a malignant condition leading to a more thorough study of the patient

Treatment of Periodic Headaches with Prostigmine Bromide—Perner and Aibel undertook the present study of the treatment of histamine headaches (reproduced by histamine injections and controlled by desensitizing the patient with small but increasing doses of histamine) after they had observed that several weeks subsequent to the cessation of histamine desensitization therapy of a patient with a typical histamine headache an attack was promptly aborted by one tablet of prostigmine bromide Some time later, when desensitization had apparently lapsed, similar treatment with prostigmine produced a typical severe cephalalgia accompanied by fulness in the back of the head, diarrhea, abdominal cramps and a mild attack of wheezing It appears that prostigmine duplicated the action of histamine in both the desensitized and sensitized phases The effect of prostigmine bromide on headaches of the migraine and histamine types was investigated on 20 patients with more or less typical histamine cephalalgias 25 with the 'migraine' type, 8 who complained of a constant tightness and fulness in the back of the neck and 7 with hypertension with pounding of the vertex of the skull, fulness or tightness in the neck muscles and the fulness in the head and ears The common denominator was a decided cutaneous sensitivity to histamine and/or acetylcholine It was hoped to 'desensitize' these patients by the oral administration of increasing doses of prostigmine bromide Accordingly, 15 mg of prostigmine bromide was dissolved in 1 ounce (30 cc) of water and administered as follows On the first day, respectively 1, 2 and 3 drops were given at morning noon and night The increase of 1 drop per dose was maintained until 30 drops was reached after which 30 drops was given each day for one week and then three times a week for an indefinite period When it was felt that the results could be improved the dose was increased to 40 drops The patients had skin tests with histamine before treatment was instituted, and repeat tests were made every week or every two weeks In 40 per cent the cutaneous reaction to injected histamine decreased with "desensitizing" doses of prostigmine Patients with definite periodic headaches of the histamine and migraine type had a definite and dramatic relief and in many it was complete for the time they were observed Several patients observed that if a mild headache did occur it could be dispelled in a few minutes by 15 drops of the solution The fulness in the head and the feeling of tightness of the neck muscles described by patients with hypertension were relieved in several The pounding of the vertex of the skull, ascribable to the hypertension, was not improved

Carminatives and Gastric Emptying—Van Liere and Northrup observed in a controlled study that 1 cc of fluidextract of ginger U S P XI given to 6 subjects in a suitable test meal significantly decreased the emptying time in 1 but not in the others. Tincture of capsicum U S P XI given to 3 subjects in doses of 0.5 cc and to 6 subjects in doses of 1 cc caused a significant decrease in the gastric emptying time of 1 subject, but that of the others was relatively unaffected. A dose of 0.3 cc of oil of peppermint U S P XI showed neither a significant increase nor a decrease in the gastric emptying time of 6 subjects. These representative carminatives may influence gastric emptying in certain subjects, but probably the emptying time of most individuals is not appreciably affected by moderate doses.

Origin of Dystopic Tissues—In explaining the genesis of anomalous tissue it is desirable to see the condition as close as possible to the period of its origin. Gruenwald describes the abnormally located tissue in 2 human embryos of the third month. The two possibilities of development, aberrant growth of a primordium from its normal point of origin and differentiation of an accessory focus from cells distant from the normal primordium of dystopic tissue, were represented by the 2 specimens. The occurrence of corticoadrenal foci in the mesonephros was illustrated by a third embryo. The study of the several types of dystopic tissue in the 3 embryos does not permit a general answer to the question of the origin of the anomaly. The developmental physiology of the tissue concerned and the region in which it is found will in most cases allow a decision between aberrant germs growing into their abnormal surround-

ings from a normally located primordium and abnormal differentiation of the local tissue gifted with the necessary developmental potencies. The latter alternative suggests a close association or mingling of tissue normally not related to each other. Consideration of the hypernephroma problem along these lines leads to the conclusion that a tissue with true corticoadrenal characteristics may well originate from originally normal renal cells. A definite and all inclusive classification of the hypernephroma as a renal or adrenal tumor is therefore neither possible nor desirable.

Fatal Sulfadiazine Urolithiasis—Rottino and La Rotonda report the first occurrence of uroliths in a human being following oral sulfadiazine therapy for pneumonia. The patient died on the twelfth hospital day of uremia caused by intrarenal disease and bilateral blockage of the ureters by crystals, which were also deposited in the pelvis and calyx of each kidney. Crystalline matter distended the tubules and caused injury to their lining epithelium. Analysis revealed that practically all the deposit was acetyl sulfadiazine, which, unlike the free form of the drug, was firm, gritty, sharp and irritating. In addition to the presence of the precipitate matter there was bilateral pyelonephritis. Sections stained for bacteria showed no organisms. Although it is not the authors' intention to ascribe the pyelonephritis to the drug, it is probable that it caused injury to tubular epithelium and was then followed by the reactive phenomenon. That there was a relationship between the tubular damage and some of the inflammatory reaction is supported by the microscopic picture, which consisted in swelling of some tubular epithelial cells, flattening of others, loss of cells with resulting ulceration, adhesion over areas of coagulum, infiltration of the latter with cellular exudate, and extension of the exudate through the tubule into the surrounding interstitium. Whether the reaction is due to the drug, to stagnant urinary products, to undisclosed bacteria or to their products is not possible to answer.

- Recent Advances in Epidemiology of Pneumococcal Infections M Finland Boston—p 307

Laennec's Cirrhosis—Ratnoff and Patek reviewed the data of eight hundred charts from five New York hospitals on which the diagnosis of "cirrhosis of the liver" appeared. The records of 386 patients showed adequate clinical evidence of cirrhosis. In 178 of these the diagnosis was established by microscopic examination of surgical or postmortem specimens, 208 were classified as presumptive cases with a palpable liver and spleen, signs of collateral venous circulation, jaundice, ascites, roentgen

signs of esophageal varices, hematemesis and laboratory tests revealing abnormal hepatic function. Certain antecedent or predisposing factors were noticed; there was an increased incidence of cirrhosis in patients of Italian and Irish stock, there was no convincing evidence of hereditary predisposition and the disease was acquired in late middle life by men two to three times as often as by women. This last factor is probably explained by the higher incidence of alcoholism in men. A coexisting nutritional deficiency may be postulated by the higher incidence of the disease in alcoholism, malaria and enteric fevers. A past history of acute hepatitis, exposure to hepatotoxins, diabetes mellitus and thyroid disease are predisposing factors of lesser importance. The most characteristic initial symptoms of Laënnec's cirrhosis were abdominal swelling and pain, anorexia, nausea, vomiting and flatulence. Other frequent symptoms were weight loss, hematemesis, epistaxis, dyspnea, nocturia, frequency and sexual disturbances. The spleen, palpable in half of the patients during life, is enlarged in about 80 per cent at necropsy. The high incidence of peripheral neuritis and of mental changes is probably due to the coexisting nutritional deficiency. Fever was present in 24 per cent of the series. Chief complications were intercurrent infection, anemia, abdominal hernia, peptic ulcer and portal vein thrombosis. The prognosis is grave after signs of decompensation appear; after ascites 47 per cent survive six months and only 32 per cent for one year, after jaundice 44 per cent live six months and 26 per cent for one year, and after hematemesis 45 per cent live six months and 28 per cent for one year. The chief causes of death were cholera, hematemesis, postoperative complications, pneumonia and intercurrent infections.

Electric Shock Therapy in Mental Disease—Myerson reports the results of treating 123 patients, 74 by the "out-patient method"—that is, the patients reported at a place fitted out in hospital fashion with nurses and a physician in attendance,

were given the shock treatment and usually went home within one or two hours. If the patient was too disturbed after treatment to return home he was transferred to a hospital for mental diseases to complete the treatment. Two patients could not return home because of injury. Outpatient care of many psychiatric patients is useful, as it often makes commitment unnecessary and is with proper safeguards as safe as inpatient care. The risk of cerebral damage by electric shock is fundamentally inconsequential when compared with the conditions treated. Electric shock is a mild procedure when compared with hypothermia, hyperthermia, lobotomy and lobectomy. Injuries have been greatly reduced. The commonest complication is fracture of a vertebral transverse process. Only 1 such fracture occurred among the 123 patients. Three cases of subdeltoid bursitis which had occurred responded to physical therapy. The most unusual injury was fracture of both acetabulums, with displacement of the heads of the femurs into the pelvis in a woman of 50, who is still under treatment. It may be of value to study the amount of calcium in the blood and the bony structure of the pelvis in certain cases. Mental disease usually warrants the treatment even when moderate organic disease of the heart and other organs is present. Electric shock treatment is of little value for the fully developed schizophrenic state, with splitting of personality, hallucinations, delusions of reference and negativistic or catatonic reactions—especially when the condition has lasted for years. It is of little advantage for paranoid psychosis and obsessive compulsive neurosis. In involutional melancholia, senile melancholia, manic depressive psychosis, chronic depression and anxiety neurosis that is a condition in which disturbance in affect or mood is the main psychopathologic feature electric shock treatment is likely to bring about definite improvement, recovery or at least remission.

Weil's Disease: Incidence, Diagnosis and Treatment: Report of Two Cases D. W. Kramer Philadelphia—p. 1298

Weil's Disease—Kramer suggests that the disparity between the incidence figures for Weil's disease in the United States and those given for certain European and Asiatic countries may be a lack of interest in the disease in this country, failure to make an accurate diagnosis and neglect in reporting authentic and recognized cases. Those interested in the subject believe that Weil's disease occurs in the United States much more frequently than the following figures indicate: 23 authentic cases from 1922 to 1940 as compared to 374 for Holland between 1924 and 1938, 248 for Britain since 1922 and similar reports for Norway, Japan, France and other countries. The figures for the United States would be increased if suspected cases were thoroughly studied and investigated by modern laboratory methods. The medical profession must become 'Weil's disease

conscious" if it is to diagnose these cases, because the disease does not always appear with the classic symptoms. Negative reports of dark field illumination or cultures of the urine and blood should not deter further investigation. The spinal fluid may reveal leptospirae. Complement fixation and agglutination tests have been improved and are helpful in making the diagnosis when other studies fail to reveal the organism. A search for leptospirae in sections obtained at necropsy is also suggested. In 1 of the 2 cases of Weil's disease reported, the diagnosis was based on the clinical picture, history of exposure, presence of similar cases in the community and positive agglutination and complement fixation tests, in the other the diagnosis was made by finding leptospirae in the urine and in sections of the spleen at necropsy. The disease should be a reportable infection. The listing of patients who have recovered from the disease and who are willing to act as donors for immune serum for persons severely ill is suggested.

Endocrine Treatment of Prostatic Hypertrophy and Cancer—Keyser reports the results in the treatment of prostatic disease with endocrine preparations and synthetic substitutes. Of 22 patients, 14 had clinically benign hypertrophy varying in symptoms from increased frequency diminished

stream and little residual urine to more or less complete retention requiring frequent catheterization, and 8 had nonspecific prostatitis associated with pus and bacteria. Of the 7 (1 with carcinoma) with complete or almost complete retention the use of an indwelling catheter and the daily administration of 1 mg of diethylstilbestrol by mouth and 1 mg intramuscularly, 2 were able to empty their bladders freely, with little residual urine with increased stream and with less nocturia in two weeks. Each of the 4 regarded as poor surgical risks was subjected to suprapubic cystostomy for drainage and then given diethylstilbestrol by mouth and intramuscularly. A few weeks later each reported that he had begun to void naturally. The suprapubic catheters were removed and the wounds healed. Of the 7 with benign hypertrophy with residual urine from zero to 3 to 4 ounces (90 to 120 cc) but with nocturia and diminished stream 6 have had decided benefits and are emptying their bladders completely, with better stream and with less frequent nocturia. None of them at present are regarded as candidates for immediate resection. Some of the 8 with nonspecific prostatitis have had definite improvement and have been relieved of dysuria, backache and general lassitude. The infection for the most part has been reduced to a small residuum, as determined by microscopic study and cultures of the prostatic secretion, but a residuum does remain. The hazards of using diethylstilbestrol are nausea, dizziness, edema of the lower extremities and a cutaneous erythematous rash, leading at times to exfoliative dermatitis. Loss of libido and oligospermia result from large doses or prolonged treatment and are contraindicated for younger or vigorous mature men. Patients receiving large doses over a long period frequently have painful swollen breasts. There are hypothetical reasons for the use of testosterone, alternating with diethylstilbestrol, in attempting treatment of an endocrine imbalance. Surgery is still the method of choice for treating prostatic hypertrophy, yet in borderline cases and in certain urologic dilemmas with such concomitant disease contraindicating surgical intervention endocrine therapy may be tried with or without suprapubic cystostomy. In nonoperable prostatic cancer the regimen will usually stay the progress of the disease to an extent at present indeterminate.

Carotenemia—Almond and Logan describe 4 cases of carotenemia in normal women after eating more than the threshold quantity of 4 pounds (1,814 Gm.) of raw carrots per week for a minimal period of seven months. The condition developed within two months in a baby fed only on the breast of its carotenemic mother. The simple three layer test of Greene and Blackford consists of equal quantities of serum, alcohol and petroleum ether shaken up in a tube. This may be left to settle as the volatile petroleum ether with its dissolved lipochromes rises to the top. If lipochromes are present in abnormal amount, this top layer will show a definite yellow tinge which is pathognomonic of carotenemia, but if the middle alcohol band is excessively yellow and is covered by a clear petroleum layer the diagnosis is jaundice.

Bee Stings in Kenya Colony—The fierceness with which native Kenya bees attack is illustrated by 3 cases that Jex-Blake reports. The numbers of the stings removed varied from two to five hundred. The amount of venom injected by a single bee sting is said by Phisalix to be 0.33 mg. The first patient suffered no more than a severe but passing inconvenience from the stings. He must have had an exceptionally high tolerance of or immunity to bee stings. The second and third patients probably had the normal degree (if there is such a thing) of sensitiveness. They became unconscious, had severe diarrhea and vomited. Two fatal cases are reported which illustrate the fact that a man who has suffered no more than the normal transient local pain and swelling after bee stings all his life may suddenly become hypersensitive to bee venom. A healthy man of 45 was stung four or five times while driving a swarm of bees out of his veranda. These stings gave rise to the usual transient painful swellings. A fortnight later he was again stung on the face four or five times, in about two minutes he collapsed and died. Artificial respiration, continued for an hour, was without effect. It seems reasonable that this patient was sensitized or rendered hypersensitive to bee venom by the first four or five stings. But for the other patient there is nothing to show why he suddenly became hypersensitive to bee venom nine months before he died (during which each stinging would become worse) after having been quite insensitive to it for twenty years. The sensitization in the first case was specific, in the other 1 it may have been specific, but nonspecific sensitization to bee venom should not be overlooked. If the signs and symptoms following severe or fatal cases of bee stings are compared with those in severe or fatal cases of serum disease they are nearly identical, and death in either case can be properly set down to anaphylactic shock.

Treatment of Phosphorus Burns—With his experience in treating 65 cases of burns caused by phosphorus, Jones advises the following procedure. The affected area should be immediately flooded with water, followed by a thorough wash with warm sodium bicarbonate solution (roughly 2 tablespoons to a pint [500 cc.] of water). Any obvious particles of phosphorus disclosed by examination in the dark should be picked off with forceps. The affected area should be swabbed with 1 per cent solution of copper sulfate and a further exploration made for phosphorus particles so revealed. The affected area should be soaked or immersed, if possible, in warm sodium bicarbonate solution for a prolonged period. The duration of this soaking

depends on the size and depth of the burn—small burns half an hour, large burns one to two hours. The area should be dressed daily with acriflavine emulsion 1:1,000. Burns near the eyes are best treated by a mask of lint soaked in sodium bicarbonate solution renewed every four hours. As soon as healing begins (seven to ten days) boroseptic ointment provides a satisfactory dressing, and its use can be continued until the scar produced is sound. Tannic acid and other coagulants do not give satisfactory results. The disadvantage of acriflavine emulsion is that individual, local and generalized cutaneous eruptions may occur, but a daily inspection will detect them, when boroseptic ointment should be substituted. With this treatment results are obtained which are comparable to those of burns caused by caustic soda and sulfuric acid. Healing is slower and scars are thinner in burns caused by phosphorus.

 Staphylococcal Pneumonia Recovery with Sulfathiazole Case J. Gordon—p. 281

Local Chemotherapy in Wounds and Burns—Matthews evaluated the local application of the sulfonamides in the treatment of wounds and burns by determining the number of living organisms recoverable daily from a known quantity of exudate. Their number was decidedly lowered even when only a trace or at most 1 mg. per hundred cubic centimeters of the drug was present in the blood stream. The urine should be examined frequently for signs of renal damage and particularly when surfaces of more than average vascularity are being treated. Chemicals such as anesol and procaine hydrochloride anesthetics should not be used during local chemotherapy, as they antagonize the sulfonamides.

Ethyl Chloride Spray in Soft Tissue Injury—While injuries to the bone and infections require rest it appears that uncomplicated injuries to soft tissue are far better treated by early active movement. Ethyl chloride sprayed over the tender area of sprain or strain will in most instances permit active movement without much discomfort. A full range of movement is carried out several times a day, though the part should not be subjected to excessive strain. McIntosh and Peirce have obtained excellent results with 109 not too extensive acute traumatic lesions of the soft tissues of the ankle, finger, thumb, wrist, elbow, acromioclavicular joint and minor injuries about the knee. If the spraying is delayed the period of disability will be prolonged. Chronic lesions may also improve. Late lesions of any of the foregoing conditions, tenosynovitis, pain of indefinite origin and the like have shown remarkable improvement. If there is no noticeable response, some other underlying condition may have been overlooked. Undoubtedly the method removes the local reflex pain, which diminishes the amount of muscle spasm and permits the muscle to function again. When this has been accomplished, sufficient lymphatic circulation is started to begin to remove the local traumatic edema. An increase in the edema may occur occasionally, particularly in sprained ankles. However, this is no indication to discontinue treatment. Ready cooperation of the patient is a great help. Soldiers may be returned to full duty in a minimum of time, while during their period of light duty they have relatively little incapacity. So far the only complication has been local irritation of the skin.

Freezing with Ethyl Chloride to Relieve Pain and Loss of Movement—Henry reports isolated instances from the records of more than 100 patients of the relief of pain from cooling or freezing with ethyl chloride spray. Many painful conditions were completely cured. Some with low back pain who had not been able to move with comfort did so easily after the treatment. Others were glad of whatever relief they got and came repeatedly to get it.

Deficiency Achromia and Diarrhea Study of Madrid Patients During War—Jimenez Garcia and Grande Covian cite reports from literature to indicate the frequent association of certain types of avitaminosis with disturbances of gastric secretion. The high incidence of deficiency diseases in Madrid during the Spanish war directed the authors' attention to the gastric function in deficiency disease. They studied the gastric chemistry of 495 patients with deficiency diseases. Few of the patients complained of gastric discomfort. The majority with hunger edema, optic neuritis and a parasthetic causalgie syndrome said nothing regarding the gastric function on being questioned. Those with pellagra and glossitis frequently had mild digestive disturbances. Secretory changes detected by examination of the gastric contents varied from hypochlorhydria to achylia. They must be ascribed to the deficient diet of the population of Madrid. These secretory gastric disturbances are the result of a deficiency in the vitamin B₂ complex. Therapeutic observations seem to indicate that nicotinic acid and vitamin A, as well as B, are incapable of restoring the normal gastric secretion of these patients. The Madrid patients with deficiency diseases frequently had severe diarrheas, but these could be combated with nicotinic acid in 94 per cent of the cases.

Hereditary Chondrodysplasia Deformans—Jimenez-Diaz and his associates report 5 cases of deforming chondrodysplasia. Two of these were observed in 2 brothers, and in these hereditary transmission from the father's side of the family could be proved. These patients presented exostoses. In the other 3 exostoses and chondromatosis were combined. It could be clearly seen in 1 case that the osteochondromatosis was secondarily superimposed on exostosis. The authors discuss the nosologic position of Ollier's disease (achondroplasia), of multiple osteochondromatosis and of exostosis disease and reach the conclusion that these disorders are different forms of the same process, which is the result of a dysplasia of the metaphyseal cartilage.

Measurement of Vitamin C by Methylene Blue Method—Castro Mendoza and Sanchez Rodriguez present a critical review of the different methods for the determination of vitamin C in blood and urine and describe a modification of the methylene blue method of Martini and Bonsignore. It consists in performing colorimetry before and after irradiation of the solution and obtaining the difference in the two readings in the calibration curve. This method has been employed since 1939, first with the aid of the colorimeter of Dubosc, then with the photometer of Pulfrich and finally with the photoelectric colorimeter of Leitz. The authors give a detailed description of the material, the required reagents, the technic and the mode of computation. They reach the conclusion that the method is the most specific for the clinical detection of vitamin C.

- Early Secondary and Late Syndrome in Diphtheria F F Inda I Nalin and Cornelia Da Rin —p 1144
*Cardiac Neurosis of Endocrine Origin E F Diaz Mindurry —p 1159

Cardiac Neurosis of Endocrine Origin—Diaz Mindurry finds that the most frequent symptoms complicating a neurosis of anxiety or depression are those of heart disease. There may be attacks of palpitation, transient anginal pain and a feeling of insufficiency of the heart. These symptoms find

no counterpart in physical signs. Clinical examination reveals transient or permanent tachycardia and extrasystoles. The teleroentgenograms and electrocardiograms are normal. Hyperthyroidism, corticoadrenal insufficiency and gonadal hormone insufficiency, alone or in combination, are the most frequent predisposing factors. Hyperthyroidism is mild and is of the abortive or oligosymptomatic type. The patients are hyperemotional and hypersensitive. They lose weight and get easily fatigued. They complain of dizziness, insomnia, nervous instability and vasomotor and other disturbances which indicate an imbalance of the basal metabolism and hyperthyroidism. As a rule the thyroid is not palpable. Arterial pressure is slightly increased. Moderate corticoadrenal insufficiency, alone or in combination with hyperthyroidism, is frequent in young patients of asthenic type with a tendency to lose weight and to be easily fatigued. The patients are depressed and hypochondriac. The arterial blood pressure is normal or low. Gonadal hormone insufficiency is frequent. Sometimes it is related to sexual life. Masturbation, sexual abstinence and, especially, coitus interruptus are causes of gonadal hormone insufficiency as a predisposing factor of cardiac neurosis. In women especially during and after the menopause, it is frequently associated with hyperthyroidism and hypertension. Glycemia tests and the quantitative determinations of ascorbic acid and blood cholesterol are of value in the diagnosis of corticoadrenal insufficiency. In the treatment it is necessary to break the vicious circle of symptoms and alter the mental attitude of the patient. Cardiac tonics, bromides and barbitol preparations are contraindicated. Exhibition of proper glandular preparations is indicated. Coffee, tea, mate tea and smoking are interdicted. Abdominal visceroposis is to be corrected and meteorism and intestinal parasitism controlled. Sometimes it is necessary to remove the patient temporarily from the family or from work. Testosterone propionate and roentgen irradiation of the hypophysis are indicated in hyperthyroidism due to hypophyseal hyperfunction. Duodothroxin, ergotamine, yohimbine and small doses of quinine or of quinidine have their indications in therapy of thyroid hyperfunction. A daily injection of 10 or 20 units of insulin, followed by administration of some dextrose in the course of diodothyroxin therapy is indicated for lean patients with hyperthyroidism and without corticoadrenal insufficiency. Adrenal cortex extract in doses of 2 mg twice a week, alone or in combination with a daily dose of 0.1 or 0.2 Gm of ascorbic acid by mouth, or of a parenteral injection of cholesterol solution, is indicated in cases of corticoadrenal insufficiency. Estrogens are indicated in ovarian and hypophyseal insufficiency, especially during the menopause. Estrogens are contraindicated in premenopausal metrorrhagias. They are indicated in small doses (from 500 to 2,000 units a day) and in combination with ovarian extracts in cases of ovarian insufficiency of young women. The results of ovarian hormone therapy are good if the treatment is persisted in for a sufficiently long period.

*Semilunar Splanchnic Anesthetic Block in Therapy of Arterial Hypertension A R Albanese R Vedoya and J Gonzalez Videla —p 1266

Semilunar Splanchnic Block in Arterial Hypertension—Albanese and his collaborators describe a technic of semilunar splanchnic infiltration which they practiced in 50 cases of hypertension. From 10 to 20 cc of a 1 per cent solution of procaine hydrochloride without epinephrine is injected with a needle 10 cm long. The infiltration is done on the left side. If the results are incomplete the right semilunar splanchnic is infiltrated. The treatment is repeated at intervals of from fifteen to sixty days. It is done on the side on which the anesthetic results were more evident. Infiltration may be performed on both sides. Results of semilunar splanchnic anesthetic block are of the same order as those of operative intervention. The subjective symptoms disappear for from fifteen to sixty days. The blood pressure falls moderately after the treatment. When it increases again the figures are lower than those observed before the treatment. The treatment is indicated for all clinical types of hypertension, even for the severe types and for the elder patients. Results of repeated injections are better than those of a single treatment.

Peripheral Vascular Disturbances—Diagnosis of vascular disorders of extremities may be difficult in the incipient stage says Philippides. The symptoms may be mistaken for those of varicose veins, flatfoot or rheumatism until the appearance of gangrene discloses the nature of the disturbance. It is important not only to detect the circulatory disturbance but to establish its organic or functional nature and the degree and location of the alterations. Methods of examination at the Kirschner clinic in Heidelberg consist of oscillometry based on the measurement of the pulse amplitude under various pressures exerted by the cuff of the hemodynamometer, the 'scala alternans' of von Recklinghausen being utilized. The values obtained by oscillometry are plotted in curves. Oscillometry is particularly valuable in incipient arterial disorders in which there are no visible circulatory signs. It is likewise useful in wounds of the extremities in which a vascular injury is suspected but in which the pulse cannot be felt because of a hematoma and edema. In traumatic aneurysms oscillometry permits of evaluation of the persisting blood perfusion of the extremity. When the oscillometric curve is pathologic, arteriography should be performed before operative intervention. Only the visualization of vessels can provide exact information regarding the severity and localization of the obliteration, the anastomoses and the collateral circulation. It is important to differentiate a spastic vascular disorder from an organic one to recognize a combination of the two and to determine whether the spasm can be modified by exclusion of the sympathetic. The determination of the cutaneous temperature under various conditions is a more sensitive method for the detection of a spastic condition than is oscillometry. There exist various methods by which the spasm can be abolished by temporary exclusion of the effect of the vasomotor fibers. These constitute the hot box test, infiltration of the stellate ganglion and paravertebral anesthesia. These methods should be employed in all circulatory disturbances of the extremities, they not only are of diagnostic and prognostic importance but also provide information regarding the proper time and the method of treatment.

Cell Cultures of Carcinomatous Pleural and Peritoneal Effusions—Hengstmann directs attention to the difficulties in the differential diagnosis of carcinomatous pleural and peritoneal effusions. Earlier investigations indicate that the individual tumor cell does not possess objective and constant characteristics which permit of its recognition. Agreement exists only with regard to recognition of tumor cells when present in groups. The occurrence of such conglomerates is not frequent. Burger, of the author's clinic in Leipzig, suggested that effusions be examined by the tissue culture method. The author describes the morphologic and functional characteristics of carcinoma cells in vitro. The morphologic characteristics of the carcinoma cell are clearer in the cell culture than in the smear. The culture also reveals the vital manifestations of the cells and their reaction to the surrounding medium particularly to the supporting tissue and to the plasma coagulum serving as a nutrient medium and the behavior of cells to one another. The various functional conditions of the fibrocytic cells are clearly differentiable from the carcinoma cells. The author examined

85 effusions of various origins. In 20 a malignant neoplasm was recognized as the cause, and in 13 carcinomatous invasion had occurred into the thoracic and abdominal serous cavities. In 5 a carcinomatous pleurisy had developed and in 8 a carcinomatous peritonitis, in 3 cases no carcinomatous dissemination was demonstrable and in the 4 remaining the question of metastatization could not be ascertained. The cell culture is convincing only when positive. A tumor cannot be excluded with certainty in the presence of a negative culture.

Effect of Thymus Hormone on Blood Sugar—Bomskov and Siem point out that the diabetogenic hormone of the anterior lobe of the hypophysis fails to produce effects in the thymus of the experimental animal has been destroyed. The diabetogenic hormone is the thymotropic hormone. It has a stimulating effect on the thymus similar to that of the gonadotropic hormone on the gonads. Bomskov and his collaborators discovered and isolated the thymus hormone. The authors found that the injection of thymus hormone is well as the injection of thymotropic hormone elevates the blood sugar content of rats and guinea pigs. There exist great individual differences and some animals showed no reaction. Nevertheless the tests indicate that the thymus hormone exerts the same effect on blood sugar as the pituitary diabetogenic hormone. With either hormone the blood sugar reaction differs individually. The hyperglycemia may be missing or only slight in spite of the existing glycosuria and of a great decrease in the glycogen content of the liver. Conditions designated as paradiabetes and hypophyseal diabetes have long been differentiated from the purely pancreatic diabetes. These atypical forms of diabetes are greatly or entirely resistant to insulin. In some of these cases in almost normal blood sugar content may be accompanied by considerable glycosuria. It is possible that increased action of the thymus hormone plays a part in these cases. Diabetes of childhood hitherto generally regarded as a hypophyseal type is believed by the authors to be a thymogenic type in view of the fact that the thymus hormone is especially active during the period of life characterized by increased growth. Acromegaly is associated with diabetes in about 40 per cent of the cases. Studies on the thymus involvement in acromegaly disclosed (1) hyperfunction of the thymus, demonstrated by the diminution of the thymus hormone in the urine, (2) impairment of the carbohydrate metabolism in man, tested in a reduced sugar tolerance and (3) lymphocytosis of the blood.

Thymus Hormone and Carbohydrate Tolerance—On the basis of clinical observations which indicated that hyperfunction of the thymus is accompanied by an abnormal dextrose tolerance, Bomskov and Schweiger made animal experiments to demonstrate that although the hyperglycemia induced by the thymus hormone is slight and fluctuating, the disturbance in the carbohydrate content can be demonstrated by tolerance tests. The injection of large doses of thymus hormone into dogs produced a great increase in alimentary hyperglycemia. The level of the dextrose tolerance curve was from two to three times as high as the normal curve. Not only was the level of the curve changed, but also the duration of the diminution of the dextrose from the blood was greatly prolonged compared to normal animals. The fact that treatment with thymus hormone is capable of inducing changes in the dextrose tolerance is another proof that the thymus hormone plays a part in carbohydrate metabolism. The experiments also corroborate clinical observations that increased diminution of the thymus hormone in the urine of adults is accompanied by a change in dextrose tolerance. The tests confirmed earlier observations that in dogs administration of thymus hormone leads to leukocytosis and lymphocytosis.

Thymus Hormone and Basal Metabolism—Bomskov and Bausch demonstrate that in spite of the fact that the thyroid and thymus have the same effect on the glycogen of the liver, the mechanism of action differs considerably. The thymus hormone exerts no influence on the basal metabolism of normal animals. The thyrogenic sugar mobilization is for the purpose of increased energy production, whereas the thymogenic sugar mobilization is for the purpose of increased deposits or growth. It is necessary to differentiate between a thyrogenic and a thymogenic metabolic status, that is, there is a difference between growth metabolism and oxidation metabolism.

Book Notices

Shock Its Dynamics Occurrence and Management By VIRGIL H. MOON, A.B. M.Sc. M.D. Professor of Pathology, Jefferson Medical College, Philadelphia. Cloth Price \$1.50 Pp 121 with 36 illustrations Philadelphia Lea & Febiger 1912

The wealth of clinical observations on shock during the first world war and the prodigious amount of research which followed has helped to clarify many debatable points, without however definitely establishing the essential cause of the syndrome. Moon reviews the various theories regarding the production of shock and presents some original concepts based on his experimental work and pathologic studies. In his discussion of the dynamics of shock Moon emphasizes two factors—damage to the endothelium of the capillaries (capillary atony) and anoxia. Hemoconcentration occurs early and tends to progress in a degree corresponding to the degree of shock. Hemoconcentration indicates abnormal permeability of endothelium and the consequent disturbance of fluid balance. Moon defines shock as “a disturbance of fluid balance, resulting in a peripheral circulatory deficiency which is manifested by a decreased volume of blood, reduced volume flow, hemoconcentration and by renal functional deficiency.” The disturbance of fluid balance may originate from diverse causes, but each of them affects primarily or secondarily the permeability of the endothelium, thus the dynamics of shock may be summed up as endothelial damage plus anoxia. The concept that a pronounced fall in arterial pressure was the central and most important feature in the syndrome has not been borne out by clinical experience. Shock in its early stages may exist in the presence of normal or even elevated arterial pressure. The acapnia theory and the decreased alkali reserve theory likewise could not be supported in a number of instances, while postmortem studies frequently failed to find fat emboli. The cause of shock in traumatic cases, according to Moon is to be seen in the absorption of the products from injured tissues. In the experience of the first world war this deficiency often was found to be out of all proportion to the apparent severity of the wound and subsided in a remarkable fashion after the amputation of a mangled limb or the debridement of other wounds.

The Special Committee on Shock and the Allied Conditions of the first world war concluded that shock in the wounded resulted from a combination of causes, including exhaustion, exposure, pain, anxiety, hemorrhage and infection, and that the absorption of products of tissue autolysis from the area of injury was the most important of these factors. The theory of traumatic toxemia finds support in the experiments of Bayliss and Cannon, who produced shock in cats by mechanical trauma to the muscles of the thigh. The previous severance of the lumbar cord did not prevent shock following trauma to the thigh muscles. This would contradict Crile's theory of vasomotor exhaustion. Evidently the fall in blood pressure was not due to painful stimulation acting on the central nervous system or to any mechanism dependent on nerve communications to the wounded area. Shock did not occur if all the vessels of the legs were ligated but occurred promptly following the release of such ligatures. Examination of the lungs for fat failed to show any evidence of fat emboli.

More recently the validity of the hypothesis of traumatic toxemia came to be questioned as the result of the experiments of Blalock, of Phemister and of their associates. They failed to demonstrate the presence of any toxic substance originating in the areas of injury and attributed the circulatory failure to local hemorrhage and not to traumatic toxemia. Cross circulation experiments were advanced as final evidence invalidating the supposition that absorption of toxic substances is a causative factor in shock resulting from trauma. Moon however, points out that much of the confusion concerning the dynamics of shock originates chiefly from four major sources. The first of these was inadequate knowledge of endothelial function and reactions and circulatory disturbance originating in the capillaries. Many surgeons regarded traumatic shock as a distinct entity and did not comprehend its relationship to circulatory failure of exactly the same type originating under other conditions. The second major cause for confusion was the failure

to distinguish between shock and the effects of hemorrhage, third, variations in blood pressure used as a criterion, and, fourth, failure on the part of the experimenters to take into account in their animal experiments the depressor effects of anesthesia and the loss of blood. Experimental technique introduced by the author in which the effects of anesthesia and hemorrhage are eliminated has demonstrated that the absorption of products derived from damaged tissues, independent of narcosis and of hemorrhage will produce the complete syndrome of shock. The author's particular contribution to the subject consists in pathologic studies of shock. He points out that hemoconcentration during life and the presence of engorged capillaries, stasis, petechiae and edema after death indicate that endothelial damage is a dynamic factor of the highest importance. He had established that shock, like other conditions of disease, is accompanied by a pattern of morphologic changes which are related etiologically to its mechanics of origin and which indicate that this function of endothelium is a major factor in its development.

Part II of the book is devoted to the discussion of the prevention, recognition and management of shock. Here the author is essentially in agreement with the accepted practice. An emphasis, however is placed on differentiation of shock from hemorrhage by means of studies of hemoconcentration. The author again and again stresses the fact that observations on hemoconcentration are most useful in indicating the incipient stage of shock. Physicians, interns and technicians are capable of making hemoglobin readings or counts of erythrocytes; many institutions have facilities for making determinations of specific gravity and of cell volume by hematocrit. The presence of hemoconcentration or hemodilution may be shown quickly and with sufficient accuracy by either of these methods.

This timely book presents in a small volume critical and more or less impartial analysis of the concepts regarding the shock syndrome. The author's literary style is distinguished by compactness and lucidity.

Annual Review of Physiology James Murray Luck, Editor. Victor E. Hall, Associate Editor. Volume IV. Published by the American Physiological Society and Annual Reviews, Inc. Cloth Price \$5 Pp 799. Stanford University P. O. Annual Reviews, Inc. 1942

This is the fourth of a series of the individual volumes of which are companion pieces to the Annual Review of Biochemistry. These books have become essential as reference works to those engaged in investigation and teaching in the biologic and medical sciences. In the present volume twenty-three topics are considered: permeability, the physiologic effects of neutron rays, physiologic aspects of genetics, developmental physiology, water metabolism, growth, energy metabolism, the physiology of the skin, the peripheral circulation, heart, blood, the digestive system, kidney, electrophysiology, the spinal cord and reflex action, the central nervous system, the autonomic nervous system, sense organs, metabolic functions of the endocrine glands, the physiology of reproduction, physiologic psychology, applied physiology, and the pharmacology of drug addiction. Most of these have been included in previous issues, but two are new—the review of the literature on water metabolism and the review of the pharmacology of drug addiction. Sections on respiration, the lymphatic system, temperature regulation, muscle, and liver and bile, which were included in previous volumes, have been omitted. It is assumed that they will be again incorporated in future editions. The space allotted to pharmacology has been cut to one article in contrast to the two or three formerly seen. An author and a subject index are available.

An immense amount of investigative work is covered by each volume of the two annual reviews, and while there is necessarily considerable overlapping, these books are too voluminous to be read in detail by the average interested person. As they stand, only specific sections are of value to most individuals. The present style makes extended reading of these books difficult, thus destroying one of the prime objects of the work—that of keeping the reader up to date over a wide range of subjects. The annual reviews would become more than mere reference lists if each reviewer was encouraged to state his own interpretations of the work covered and to gather the results listed into a unified picture (even though that picture

The author describes the morphologic and functional characteristics of carcinoma cells in vitro. The morphologic characteristics of the carcinoma cell are clearer in the cell culture than in the smear. The culture also reveals the vital manifestations of the cells and their reaction to the surrounding medium, particularly to the supporting tissue and to the plasma coagulum serving as a nutrient medium and the behavior of cells to one another. The various functional conditions of the fibrocytic cells are clearly differentiable from the carcinoma cells. The author examined

85 effusions of various origins. In 20 a malignant neoplasm was recognized as the cause, and in 13 carcinomatous invasion had occurred into the thoracic and abdominal serous cavities. In 5 a carcinomatous pleurisy had developed and in 8 a carcinomatous peritonitis, in 3 cases no carcinomatous dissemination was demonstrable and in the 4 remaining the question of metastatization could not be ascertained. The cell culture is convincing only when positive. A tumor cannot be excluded with certainty in the presence of a negative culture.

Effect of Thymus Hormone on Blood Sugar—Bomskov and Stein point out that the diabetogenic hormone of the anterior lobe of the hypophysis fails to produce effects if the thymus of the experimental animal has been destroyed. The diabetogenic hormone is the thymotropic hormone. It has a stimulating effect on the thymus similar to that of the gonadotropic hormone on the gonads. Bomskov and his collaborators discovered and isolated the thymus hormone. The authors found that the injection of thymus hormone as well as the injection of thymotropic hormone elevates the blood sugar content of rats and guinea pigs. There exist great individual differences and some animals showed no reaction. Nevertheless, the tests indicate that the thymus hormone exerts the same effect on blood sugar as the pituitary diabetogenic hormone. With either hormone the blood sugar reaction differs individually. The hyperglycemia may be missing or only slight in spite of the existing glycosuria and of a great decrease in the glycogen content of the liver. Conditions designated as paradiabetes and hypophyseal diabetes have long been differentiated from the purely pancreatic diabetes. These atypical forms of diabetes are greatly or entirely resistant to insulin. In some of these cases an almost normal blood sugar content may be accompanied by considerable glycosuria. It is possible that increased action of the thymus hormone plays a part in these cases. Diabetes of childhood hitherto generally regarded as a hypophyseal type, is believed by the authors to be a thymogenic type in view of the fact that the thymus hormone is especially active during the period of life characterized by increased growth. Acromegaly is associated with diabetes in about 40 per cent of the cases. Studies on the thymus involvement in acromegaly disclosed (1) hyperfunction of the thymus, demonstrated by the elimination of the thymus hormone in the urine, (2) impairment of the carbohydrate metabolism manifested in a reduced sugar tolerance, and (3) lymphocytosis of the blood.

Thymus Hormone and Carbohydrate Tolerance—On the basis of clinical observations which indicated that hyperfunction of the thymus is accompanied by an abnormal dextrose tolerance, Bomskov and Schweiger made animal experiments to demonstrate that, although the hyperglycemia induced by the thymus hormone is slight and fluctuating, the disturbance in the carbohydrate content can be demonstrated by tolerance tests. The injection of large doses of thymus hormone into dogs produced a great increase in alimentary hyperglycemia. The level of the dextrose tolerance curve was from two to three times as high as the normal curve. Not only was the level of the curve changed, but also the duration of the elimination of the dextrose from the blood was greatly prolonged compared to normal animals. The fact that treatment with thymus hormone is capable of inducing changes in the dextrose tolerance is another proof that the thymus hormone plays a part in carbohydrate metabolism. The experiments also corroborate clinical observations that increased elimination of the thymus hormone in the urine of adults is accompanied by a change in dextrose tolerance. The tests confirmed earlier observations that in dogs administration of thymus hormone leads to leukocytosis and lymphocytosis.

Thymus Hormone and Basal Metabolism—Bomskov and Bausch demonstrate that, in spite of the fact that the thyroid and thymus have the same effect on the glycogen of the liver, the mechanism of action differs considerably. The thymus hormone exerts no influence on the basal metabolism of normal animals. The thyrogenic sugar mobilization is for the purpose of increased energy production, whereas the thymogenic sugar mobilization is for the purpose of increased deposits or growth. It is necessary to differentiate between a thyrogenic and a thymogenic metabolic status, that is, there is a difference between growth metabolism and oxidation metabolism.

Book Notices

Shock Its Dynamics Occurrence and Management By WILLIAM B. MOON, M.D. Professor of Pathology Jefferson Medical College Philadelphia Cloth Price \$1.50 Pp 321 with 36 illustrations Philadelphia Lea & Febiger 1912

The wealth of clinical observations on shock during the first world war and the prodigious amount of research which followed has helped to clarify many debatable points, without however definitely establishing the essential cause of the syndrome. Moon reviews the various theories regarding the production of shock and presents some original concepts based on his experimental work and pathologic studies. In his discussion of the dynamics of shock Moon emphasizes two factors: damage to the endothelium of the capillaries (capillary atony) and anoxia. Hemoconcentration occurs early and tends to progress in a degree corresponding to the degree of shock. Hemoconcentration indicates abnormal permeability of endothelium and the consequent disturbance of fluid balance. Moon defines shock as "a disturbance of fluid balance, resulting in a peripheral circulatory deficiency which is manifested by a decreased volume of blood, reduced volume flow, hemoconcentration and by renal functional deficiency." The disturbance of fluid balance may originate from diverse causes, but each of them affects primarily or secondarily the permeability of the endothelium, thus the dynamics of shock may be summed up as endothelial damage plus anoxia. The concept that a pronounced fall in arterial pressure was the central and most important feature in the syndrome has not been borne out by clinical experience. Shock in its early stages may exist in the presence of normal or even elevated arterial pressure. The respiration theory and the decreased alkali reserve theory likewise could not be supported in a number of instances, while postmortem studies frequently failed to find fat emboli. The cause of shock in traumatic cases, according to Moon, is to be seen in the absorption of the products from injured tissues. In the experience of the first world war this deficiency often was found to be out of all proportion to the apparent severity of the wound and subsided in a remarkable fashion after the amputation of a mangled limb or the debridement of other wounds.

The Special Committee on Shock and the Allied Conditions of the first world war concluded that shock in the wounded resulted from a combination of causes, including exhaustion, exposure, pain, anxiety, hemorrhage and infection, and that the absorption of products of tissue autolysis from the area of injury was the most important of these factors. The theory of traumatic toxemia finds support in the experiments of Bayliss and Cannon, who produced shock in cats by mechanical trauma to the muscles of the thigh. The previous severance of the lumbar cord did not prevent shock following trauma to the thigh muscles. This would contradict Crile's theory of vasomotor exhaustion. Evidently the fall in blood pressure was not due to painful stimulation acting on the central nervous system or to any mechanism dependent on nerve communications to the wounded area. Shock did not occur if all the vessels of the legs were ligated but occurred promptly following the release of such ligatures. Examination of the lungs for fat failed to show any evidence of fat emboli.

More recently the validity of the hypothesis of traumatic toxemia came to be questioned as the result of the experiments of Blalock, of Phemister and of their associates. They failed to demonstrate the presence of any toxic substance originating in the areas of injury and attributed the circulatory failure to local hemorrhage and not to traumatic toxemia. Cross circulation experiments were advanced as final evidence invalidating the supposition that absorption of toxic substances is a causative factor in shock resulting from trauma. Moon, however, points out that much of the confusion concerning the dynamics of shock originates chiefly from four major sources. The first of these was inadequate knowledge of endothelial function and reactions and circulatory disturbance originating in the capillaries. Many surgeons regarded traumatic shock as a distinct entity and did not comprehend its relationship to circulatory failure of exactly the same type originating under other conditions. The second major cause for confusion was the failure

to distinguish between shock and the effects of hemorrhage, third, variations in blood pressure used as a criterion, and, fourth, failure on the part of the experimenters to take into account in their animal experiments the depressor effects of anesthesia and the loss of blood. Experimental technique introduced by the author in which the effects of anesthesia and hemorrhage are eliminated has demonstrated that the absorption of products derived from damaged tissues, independent of narcosis and of hemorrhage, will produce the complete syndrome of shock. The author's particular contribution to the subject consists in pathologic studies of shock. He points out that hemoconcentration during life and the presence of engorged capillaries, stasis, petechiae and edema after death indicate that endothelial damage is a dynamic factor of the highest importance. He had established that shock, like other conditions of disease, is accompanied by a pattern of morphologic changes which are related etiologically to its mechanics of origin and which indicate that this function of endothelium is a major factor in its development.

Part II of the book is devoted to the discussion of the prevention, recognition and management of shock. Here the author is essentially in agreement with the accepted practice. An emphasis, however, is placed on differentiation of shock from hemorrhage by means of studies of hemoconcentration. The author again and again stresses the fact that observations on hemoconcentration are most useful in indicating the incipient stage of shock. Physicians, interns and technicians are capable of making hemoglobin readings or counts of erythrocytes, many institutions have facilities for making determinations of specific gravity and of cell volume by hematocrit. The presence of hemoconcentration or hemodilution may be shown quickly and with sufficient accuracy by either of these methods.

This timely book presents in a small volume critical and more or less impartial analysis of the concepts regarding the shock syndrome. The author's literary style is distinguished by compactness and lucidity.

Annual Review of Physiology James Murray Luck, Editor Victor E. Hall, Associate Editor Volume IV Published by the American Physiological Society and Annual Reviews Inc. Cloth Price \$5 Pp 709 Stanford University P. O. Annual Reviews Inc. 1942

This is the fourth of a series the individual volumes of which are companion pieces to the Annual Review of Biochemistry. These books have become essential as reference works to those engaged in investigation and teaching in the biologic and medical sciences. In the present volume twenty-three topics are considered: permeability, the physiologic effects of neutron rays, physiologic aspects of genetics, developmental physiology, water metabolism, growth, energy metabolism, the physiology of the skin, the peripheral circulation, heart, blood, the digestive system, kidney, electrophysiology, the spinal cord and reflex action, the central nervous system, the autonomic nervous system, sense organs, metabolic functions of the endocrine glands, the physiology of reproduction, physiologic psychology, applied physiology, and the pharmacology of drug addiction. Most of these have been included in previous issues, but two are new: the review of the literature on water metabolism and the review of the pharmacology of drug addiction. Sections on respiration, the lymphatic system, temperature regulation, muscle, and liver and bile, which were included in previous volumes, have been omitted. It is assumed that they will be again incorporated in future editions. The space allotted to pharmacology has been cut to one article in contrast to the two or three formerly seen. An author and a subject index are available.

An immense amount of investigative work is covered by each volume of the two annual reviews and while there is necessarily considerable overlapping, these books are too voluminous to be read in detail by the average interested person. As they stand, only specific sections are of value to most individuals. The present style makes extended reading of these books difficult, thus destroying one of the prime objects of the work: that of keeping the reader up to date over a wide range of subjects. The annual reviews would become more than mere reference lists if each reviewer was encouraged to state his own interpretations of the work covered and to gather the results listed into a unified picture (even though that picture

would be a purely personal one) in a summary of sufficient length to be of significant value. This is especially necessary since in most cases the review of any single publication is too brief to give the reader the information necessary to judge accurately the worth of the data reported. The reviewers of three of the subjects covered in the present volume have made a start in this direction, the sections on the central nervous system, physiologic psychology and the pharmacology of drug addiction present brief summaries.

In its present form the book is invaluable to workers interested in special fields, it is of little value to the busy reader attempting to keep himself up to date in the many aspects of physiology.

The Discovery of the Orgone. Volume I. The Function of the Orgasm. Sex Economic Problems of Biological Energy. By Wilhelm Reich. Translated from the German Manuscript by Theodore P. Wolfe. Cloth. Price \$3. Pp. 368 with 18 illustrations. New York: Orgone Institute Press, 1942.

This book is intended primarily for psychoanalytically oriented students of human behavior problems. In the beginning the author says "the Freudian 'unconscious' is actually tangible in the form of vegetative impulses and bodily sensations. A psychic experience may produce a lasting alteration in an organ." Freud's theory of the etiology of the neurosis is not complete. Every individual who has managed to preserve a bit of naturalness knows that there is only one thing wrong with neurotic patients: the lack of full and repeated sexual satisfaction.

The severity of any kind of psychic disturbance is in direct relation to the disturbance of genitality. The prognosis depends directly on the possibility of establishing the capacity for full genital satisfaction. Probably few if any psychoanalysts will completely disagree with these formulations.

His work suffers from too much and often quite irrelevant rehashing of the author's own personal problems, particularly those involving his disappointment with his teacher, Freud. Despite these irrelevances the book offers material for serious thought and careful investigation with clinical material by those engaged in treating patients with psychologic problems. Whether these problems are of an obviously emotional nature or are hidden under the symptoms or so called organ neurosis, Reich has contributed greatly to the understanding of human behavior problems and to the techniques of therapy, therefore it is probably wise to put to one side the political aspects presented in this work and to give thoughtful attention to the main thesis.

The book contains a comprehensive table of significant events leading to the present work arranged chronologically from 1861 to 1941 by the translator, Theodore P. Wolfe, whose translation, preface and annotations are all exceedingly well done. There is an appended glossary which may aid the uninformed reader in understanding Reich's terminology, which at times becomes difficult to follow. It is unfortunate that the author chose to disregard the constructive scientific contributions to research in the study of psychophysiologic problems made by Alexander, Simmel, French, Karl and William Menninger, Felix Deutsch, Fenechal, Dunbar, Wilson, Daniels, Saul and Benedek, among others. Reich seems to forget that he is not alone in contributing to scientific psychologic research. Could it be that he is so obsessed with his own theories and his own contributions that he does not "familiarize" himself with the recent and current literature or that he just ignores the contributions of others?

New Technical and Commercial Dictionary. Compiled by Antonio Perol Guerrero. Industrial engineer. Escuela central de Ingenieros. Madrid. Part I. Spanish-English. Part II. English-Spanish. Part III. Conversion Tables of Weights, Measures and Monetary Units. Fabricoid. Price \$10. Pp. 600. Brooklyn. Editorial tecnica unida. 1942.

In the preface the author points out that the introduction of new products, machinery and equipment into Pan American countries has exerted a tremendous influence on the Spanish language. Because there were no corresponding Spanish words, English words have been adopted bodily for most technical terms. This dictionary selects fifty thousand words commonly used in technical and commercial activities. It fails wholly as a helpful work in the field of medicine, since that field was obviously so special that medical words had to be largely eliminated. One searches in vain for such terms as allergy, immunology, viruses and many similar terms more recently in medical usage. After all, with the speed of advancement of modern science, even fifty thousand words are a relatively small selection.

Clinical Cardiology with Special Reference to Bedside Diagnosis. By William Dressler, M.D., Attending Cardiologist, Israel Zion Hospital, Brooklyn. Cloth. Price \$7.00. Pp. 692 with 108 illustrations. New York & London: Paul B. Hoeber, Inc., 1942.

Whoever opens this new book on clinical cardiology with some hesitation, because he feels that there is an abundance of excellent modern textbooks on the subject without apparent need for an additional one, will soon recognize that many chapters represent a new approach yielding new information and thus fully justifying another volume on clinical cardiology. Through out the work the authority of an experienced clinician and keen observer who is familiar with the most recent progress in the entire field of cardiology can be felt. He has made valuable contributions. Dressler places the predominant weight on the recognition and correct interpretation of signs at the bedside. Instead of replacing the simple methods of inspection, palpation, percussion and auscultation gained by more accurate laboratory methods, he shows convincingly how the information gained by methods such as pulse recordings, electrocardiography and fluoroscopy, when applied at the bedside, can be used to improve and to simplify our methods of physical examination. This is best illustrated by the chapters on pulsatory phenomena of the chest wall and pulsations of the veins. The diagnostic gain of such an approach is made clear in the chapters dealing with lesions of the tricuspid valve. The book is divided in three main parts, on methods of examination, general pathology and special pathology, with a thorough and clear discussion of all common and less common conditions. To this some other chapters are added, including one on pregnancy and heart disease and one on surgery and heart disease. The number of pages might have been reduced by omitting frequent repetitions, but by such a procedure the individual chapters would have lost their completeness. Relatively little space is given to electrocardiography, however, all references made to the information obtainable by this method show the expert in this particular field. Dressler's book is a valuable addition to the available excellent textbooks on cardiology. It can be highly recommended to the student who is particularly interested in bedside diagnosis of heart disease, it will be read with benefit by the experienced cardiologist.

Macular Proliferation (Pseudotumour) and Closely Related Pictures of Disease (Reinheits Circinata Coats Disease Etc.). By Stig Holm, M.D. Acta ophthalmologica supplementum XX. Paper. Pp. 30 with 13 illustrations. Copenhagen: Ejnar Munksgaard, 1941.

Many years ago the ophthalmologists of the Scandinavian countries, under the leadership of the late Prof. K. K. K. Lundsgaard, founded the *Acta ophthalmologica*, a journal for the purpose of making their publications available in the more frequently used languages of the world. Each article is published in German, French or English according to the linguistic ability of the author. Once or twice a year a supplement of seventy-five to one hundred pages is issued free to regular subscribers. This contains a single research or compilation article that is too long for the regular issues but is sufficiently valuable to justify publication. The *British Journal of Ophthalmology* has followed this example and now the *Transactions of the American Academy of Ophthalmology and Oto-Laryngology* is planning to do likewise. On the whole, these supplements are extremely valuable. This supplement, based on the report of a case studied in the eye clinic and the histologic institute of the University of Lund in Sweden, contains an excellent description of the case, well illustrated in black and white, and a critically analytic study of the resemblance of this to similar retinal pictures, variously described and labeled with the names of different men. The textual material of the brochure is of interest only to ophthalmologists, but the character of the journal and the type of supplements are of interest to all who are interested in the literature of medicine.

Síndromes clínicos radiológicos de retracción pulmonar. Por el Dr. Angel I. Brisco Capurro. Tesis del doctorado. Universidad nacional de Buenos Aires. Facultad de ciencias médicas. Paper. Pp. 37 with 25 illustrations. Buenos Aires, 1939.

This is an interesting pamphlet including twenty-five excellent reproductions of roentgenograms illustrating graphically the various phenomena of unilateral pulmonary contraction, total and partial. Of especial interest are the ingenious diagrams illustrating the direction in which the contractions or retractions occur in the different lobes of the lung. This seems to follow certain lines except when deterred by limiting adhesions.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

KENNY TREATMENT AND CONVALESCENT SERUM FOR POLIOMYELITIS

To the Editor—Will you please give me the number of successful cases of poliomyelitis treated by the Kenny method? Also the number of failures? Is there any advantage in using the convalescent serum? How long should the Kenny treatment be kept up? John A. Colteaux M.D., Roberts III

ANSWER—Complete figures are not available as to the number of patients treated successfully or otherwise with the Kenny method. This method was not made available to the medical profession in general until 1942. During this year most of the 3,200 cases reported to date have been treated by the Kenny method or some modification. About five hundred physicians, nurses and physical therapy technicians have been taught the Kenny method. These represent every state in the union. It is their opinion that the Kenny method is superior to immobilization. Figures are not available as to "failures."

The Kenny method is not a cure but is symptomatic treatment using heat to overcome "spasm" and pain and early muscle reeducation to overcome "alienation" (apparent paralysis) and "incoordination" (substitution of well muscles for those affected by the disease). Treatment is continued for as long as the symptoms persist. Moist heat is applied for several weeks to several months. The muscle reeducation program may have to be continued for a year or more.

The percentage of true paralysis will depend on the nature of the outbreak and individual factors rather than on the treatment applied, since no form of treatment can be expected to restore function when there has been massive destruction of anterior horn cells. These cases usually make up 5 to 20 per cent of all reported. The other 80 to 95 per cent make a better recovery under the Kenny method than under one of rigid immobilization.

Convalescent serum apparently has not been of any proved value either in clinical practice or in the experimental disease in laboratory animals. While it is used in many localities and is still widely advocated, its proponents usually defend their action on the basis that "it does no harm." Mice, cotton rats and monkeys infected with poliomyelitis virus had neither the death rate, the incidence of paralysis nor the incubation period altered by use of massive doses of convalescent serum.

CARBON DIOXIDE COMBINING POWER OF PLASMA

To the Editor—In the laboratory at our hospital we had occasion to determine the carbon dioxide combining power of a plasma that had stood in the ice box for about eighteen hours before being examined. Slight hemolysis had occurred and the reading was four volumes per cent. The question arose: Does the plasma alter sufficiently on standing and with slight hemolysis to lower or alter appreciably in any way the result obtained? I am aware of the necessity of protecting blood under a film of oil to determine the carbon dioxide capacity of the blood, but that is not what I mean, I am interested in the carbon dioxide combining power. An opinion and references will be appreciated.

Charles Abler, M.D. New York

ANSWER—This question was answered by Van Slyke and Cullen in their original paper (*J Biol Chem* 30:309, 1917) and has been substantiated by the practical experience of many others. Van Slyke and Cullen state that "plasma can be kept for a long time without alteration in its carbon dioxide binding capacity. Sterile plasma, if kept cold in tubes that have been paraffined in order to avoid solution of alkali from the glass, can be preserved for over a week without alteration in its carbon dioxide capacity. Plasma in ordinary glass can be kept for only a few hours, as sufficient alkali dissolves from the glass in longer intervals to increase measurably the carbon dioxide capacity." Slight hemolysis should not have more than a slight influence on the carbon dioxide combining power. Plasma should not give a significantly lowered carbon dioxide combining power after refrigeration for eighteen hours if it has been properly reequilibrated with alveolar air. Any change would be likely to be a slight elevation, owing to absorption of alkali from the glass.

RAMPANT DENTAL CARIES

To the Editor—In a boy aged 4 premature decay of all teeth has taken place since the age of 2. This occurred in definite groups, first the upper front then the rear and finally all the lower front teeth. All have been removed except a few which will soon have to undergo the same thing. The mother is quite concerned lest the same fate overtake the permanent teeth when they appear. Can you furnish any information on this?

M.D. Minnesota

ANSWER—Rampant dental caries such as that described is one of the unsolved and perplexing medicodental problems. Ordinary caries can be adequately controlled by early and consistent dental care and oral hygiene. However, rampant caries spreads so rapidly that the dental care and oral hygiene must be unusually meticulous, although this does not guarantee control of caries.

The literature does not contain an adequate solution to this problem, though it indicates that systemic factors affecting the character of the saliva may be responsible, although no definite proof has ever been established. Rampant caries as well as altered salivary composition may be present in hypothyroidism and mongolism but also in normal children. There is some indication that there may be a relationship between thiamine deficiency and rampant caries.

Early and consistent dental attention to remove the decay as soon as it appears will tend to decrease the rate of its spread. Careful oral hygiene will help. The physician should reduce the carbohydrate intake and insist that no candies be eaten. Salivary analysis may reveal some clue and should be supplemented by complete blood chemistry and urine analysis. The problem is basically a medical one but the clues are scanty.

ANEMIA AND CRAVING FOR ICE

To the Editor—What would be the effect on the blood making organs of the ingestion of large amounts of ice? A widow aged 43 the proprietress of an ice cream parlor eats 10 cents worth of chopped ice (10 pounds) daily. She has developed a craving for ice. When her own store is closed she will often visit another soda fountain order soda leave the soda and eat the ice. The patient's history reveals no serious illnesses, accidents or operations. She had an attack of syncope a month ago and at present complains of weakness, palpitation, shortness of breath, backache, constipation and poor appetite, all of one month's duration. Her blood pressure is 100 systolic 60 diastolic the hemoglobin is 4.3 Gm per hundred cubic centimeters or 21.8 per cent the color index 0.5 the erythrocyte count 2,660,000 the leukocyte count 4,750 with 71 per cent polymorphonuclear leukocytes 2 per cent eosinophils and 27 per cent small lymphocytes. There is slight abnormality in size and shape. There is vacuolation of the cells, and the nuclear index is 10.8 with a slight shift to the left. The Wassermann reaction is negative. The urine contains only a few white blood cells. The physical examination is otherwise negative. Do you think that the ingestion of ice is the cause of the severe secondary anemia and other symptoms?

M. H. Axilrod M.D., Atlantic City N. J.

ANSWER—There appears to be no reference in current books on psychiatry to a pathologic appetite for ice. It seems rather unlikely that the ice per se would cause any appreciable anemia.

Most of the patient's symptoms could result from the severe anemia. It is apparently a microcytic hypochromic type of anemia, which occurs in iron deficient states. Achlorhydria is frequently a conditioning factor in this type of anemia. Either an iron deficiency could have been carried over from before the menopause or there might have been more recent blood loss. Stool examinations and gastrointestinal x-ray examination are indicated.

As decreased temperatures in the stomach have been shown to reduce gastric acidity (*Surg, Gynec & Obst* 71:172 [Aug] 1940), one wonders whether prolonged ingestion of ice might have caused an achlorhydria in this case. Also has there been a general dietary restriction as a result of the abnormal appetite? The ice may conceivably be a secondary factor in the production of the anemia.

EPINEPHRINE AND AMINOPHYLLINE FOR ASTHMA

To the Editor—What is the difference in indications for epinephrine and aminophylline in acute bronchial asthma? What is the intravenous dose of the latter?

Eugene Talmage M.D. Santa Monica Calif

ANSWER—Aminophylline is used for the relief of the attacks of asthma usually only when the patient fails to respond to subcutaneous injections of epinephrine solution. This is primarily because of the greater ease of administering a drug subcutaneously rather than intravenously, as is required when aminophylline is given. When patients fail to respond to epinephrine solution, it is unwise to continue the administration of epinephrine since it increases the danger of producing severe intractable asthma (status asthmaticus). It is advisable in such cases to avoid the use of epinephrine solution for about twenty-four hours.

and to use aminophylline intravenously, together with other measures for relief. In many cases, after twenty-four hours of avoidance of epinephrine, it will again give relief. Epinephrine can then be given, alternating, if necessary, with aminophylline to avoid overdosing with epinephrine solution. In addition to the indication mentioned, aminophylline will in some cases produce a longer relief period than epinephrine solution. This is an individual variation and is not based on any difference in the type of asthma.

The dose of aminophylline for intravenous use is between $3\frac{1}{2}$ and 7 grains (0.22 and 0.45 Gm.) In most cases the $3\frac{1}{2}$ or $3\frac{3}{4}$ grain ampules (10 cc.) will give relief. Some cases may require the 7 grain ampules. If injected slowly, only minor disturbing symptoms (faintness, flushing or precordial distress) will occur during the injection. Great care should be taken to avoid subcutaneous spilling of the solution as the material is quite irritating to the subcutaneous tissues.

CELIAC DISEASE AND VITAMIN DEFICIENCIES

To the Editor—During the past four years some interesting observations have come to my attention while using vitamins B and K which I should like to record with the purpose of inquiring whether any similar observations have been made. In the treatment of 5 cases of celiac disease in children a prompt improvement occurred following the use of vitamin B complex. The stools decreased in size they assumed normal color the abdominal contour returned to normal the appetite increased and in a matter of three to six months the children became quite normal. In a number of patients who complained of fatigue and whose physical examinations were otherwise negative except for a progressive lowering of the blood pressure on changing from the reclining to the erect position (myasthenia gravis type of response) I have noticed that a course of B complex reversed this blood pressure reaction in most of the cases and at the same time caused a lessening of the fatigue. In 3 cases presenting the nephrotic syndrome of albuminuria hypoproteinemia water retention and reversal of the albumin globulin ratio I have noticed that the addition of vitamin K to whatever therapeutic regimen was being followed caused a disappearance of all these abnormal findings within a comparatively short time. I would appreciate any references in the literature which may be available relative to these notes.

William J. Forbes M.D. Lakewood Ohio

ANSWER—Attention may be called to a recent paper on this subject. May and his co-workers (*J. Pediat.* 21:289 [Sept.] 1942) found that vitamin B complex given parenterally or by mouth caused a definite improvement in such patients. It allowed them to take essentially normal diets. The authors concluded tentatively that celiac disease is a deficiency disease relieved by these vitamins and by a crude extract of liver.

Impairment of intestinal functions of various kinds have been produced experimentally in animals by vitamin B deficient diets. These disabilities can certainly be remedied by the administration of vitamin B complex (McCarison Robert Studies in Deficiency Disease, New York, University Press, 1921). Crude liver extract is claimed to have a beneficial effect in celiac disease comparable to its effects in the steatorrhea of sprue—possibly in part at least because of its content of certain constituents of the vitamin B complex.

As far as can be determined, no report has been published pertaining to the value of vitamin K in the treatment of the nephrotic syndrome. Since patients with long standing nephrosis nearly always suffer from some degree of undernutrition (owing primarily to poor appetite) and since some authors believe that liver function is impaired in this syndrome, it would not be surprising to find a favorable response to vitamin K administration. It should be noted, however, that hypoproteinemia is not characteristic of the nephrotic syndrome and patients or animals suffering from vitamin K deficiency do not ordinarily show signs of nephrosis.

OBESITY IN EUNUCHOID INDIVIDUALS

To the Editor—Can the obesity in eunuchoid individuals be controlled by diet and systematic physical exercise or can the condition be controlled only by the proper substitutive therapy?

Harry Rand M.D. Springdale Utah

ANSWER—If by obesity general obesity is meant, it is not clear that hypogonadism itself is responsible. When obesity and hypogonadism coexist, every effort should be made to demonstrate a hypothalamic lesion. In the absence of such evidence the two symptoms may be tentatively regarded as fortuitously associated. Regardless of the lesion, demonstrated weight loss will occur if dietary measures are undertaken. Localization of fat deposits about the mons and hips and in the breasts however may be properly regarded as favored by hypogonadism. These deposits are sensitive to undernutrition but may be less so than fat deposited elsewhere. The extent that substitution therapy favors resorption of such localized fat is not too well established, but such an influence may be expected. It must be coupled with suitable dietary restriction.

ABNORMALITY OF FINGERNAIL FROM TRAUMA

To the Editor—We have under our care at this army hospital a man who confused his finger in a doorway, causing him to lose his nail. The new nail is growing in the opposite direction, that is toward the middle phalanx. I do not have access to the literature at this post. I would appreciate any references or reprints of this condition described in the literature if there is anything available.

Glenn A. Delbert, Lieutenant M.C., A.U.S.

ANSWER—Although there are many references in the literature to nail abnormalities, those due to accident are rare. Only one reference has been found to a displacement similar to the one described in the query. A case of lupus vulgaris of the left little finger caused total destruction of the finger except for a dark brown nail 4 mm wide at the base and pointed, located at the level of the metacarpophalangeal joint. Its direction of growth was toward the shoulder (Heller J. Die Krankheiten der Nagel Handb. d. Haut u. Geschlechtsthr. 13:363, Berlin, Julius Springer, 1927). An excellent article on plastic surgery of the finger and toe nails is that by J. E. Shuchan, (Replacement of Thumb Nail, *The Journal*, April 13, 1929, p. 1253).

TREATMENT OF RECURRENT HYPERTHYROIDISM

To the Editor—Please advise me regarding the latest opinions relative to the treatment of hyperthyroidism by other than surgical measures. A man aged 35 who was operated on two years ago, now has a return of the condition with considerably more enlargement of the gland and he dreads further surgical work. He read in *Hygieia* that some success had been obtained by roentgen treatments. I would appreciate any information which will help us reach a conclusion.

R. E. Hale, M.D. Bellamy Ala

ANSWER—In most instances the treatment of hyperthyroidism is subtotal thyroidectomy after adequate preparation. This applies to recurrences as well as to the original attack. Roentgen therapy might be tried if operation is refused, but it has the disadvantage that a considerable length of time is necessary to determine whether or not it will be successful. Moreover, there is some danger of burning the skin, which may happen under the most carefully controlled circumstances. If the general condition of the patient is good and there is no vocal cord paralysis there should not be any hesitation in urging further operation.

VITAMIN C AND DERMATITIS

To the Editor—Is it possible for a deficiency in vitamin C or ascorbic acid to cause acneiform or any other dermatitis of the face?

M.D., New York

ANSWER—It is not generally believed that deficiency in vitamin C causes acneiform or any other dermatitis. It is possible that a deficiency in the vitamin may allow dermatitis to appear, whereas it might not be visible under optimal conditions. There is no proof of such a theoretical relationship; in fact, there is no good evidence for it. Ordinarily vitamins should be administered only when there is a demonstrated vitamin deficiency and not otherwise.

LYMPHEDEMA AFTER SPRAINED ANKLE

To the Editor—On page 728 of the October 31 issue of *The Journal* an inquiry is made concerning the cause of swelling of the ankle persisting long after a sprain was sustained. The reply concerns itself with local mechanical abnormalities as the basis for the persistence of swelling. Too little attention is paid to the existence of thrombophlebitis in the deep veins of the foot, ankle and calf in some of these cases. This explanation of the swelling will better fit the circumstances in some of these cases than mechanical instability. The diagnosis can be suspected on the clinical evidence alone and can be made with certainty by venographic visualization. If the diagnosis is confirmed the treatment is that for thrombophlebitis for which the newer methods such as sympathetic nerve block and vein ligation have recently been introduced. The appended references discuss the subject in adequate detail.

INTRAVENOUS INJECTION OF POOLED NORMAL PLASMA OR SERUM

IS IT DANGEROUS?

WILLIAM THALHIMER, M D
NEW YORK

An extensive, worldwide experience has demonstrated that the therapeutic intravenous administration of large amounts of properly prepared, pooled human plasma or serum to patients belonging to all four blood groups is followed by only a small percentage of reactions of any kind. Most of these reactions are either so mild as to be insignificant or only moderate in degree, insufficient to cause any real harm to the patient. Certainly it has been shown that no one in genuine need of this type of intravenous therapy should be denied it because of the possible occurrence of one of these reactions.

Nevertheless, several recent publications¹ have questioned the opinion derived from this experience on the basis of the possible danger from the injection of incompatible agglutinins or incompatible A or B substances.

The important question and in fact, the only question is whether it is safe to administer pooled plasma or serum intravenously in large amounts to an individual who is in urgent need of this type of therapy regardless of his blood group. The corollary of this is: Are possible incompatible agglutinins or the agglutinogens in A or B substances present in pooled serum or plasma in sufficiently strong concentration to be a possible danger to the patient?

Plasma or serum prepared on a large scale can be produced satisfactorily and economically only when large pools are prepared by mixing the material obtained from many donors belonging to all four blood groups.

Only in small blood banks does occasion ever arise to use plasma obtained from only one donor. Whereas the problem of the advisability of administering plasma obtained from a single donor, regardless of the blood group of the recipient, is an important one for a hospital, this does not particularly concern us here.

We must discuss mainly the possible danger from the intravenous injection of large amounts of pooled plasma or serum containing low titers of incompatible agglu-

tinins that might cause specific intravascular phenomena and therefore possibly injure the patient, and whether either the A or B substances can be present in sufficiently large amounts to cause a serious reaction or harm to a patient receiving these intravenously.

It may be well to make clear at the outset that it is quite well recognized that any material injected intravenously may cause a fever-chill, or even more severe, reaction. In fact, the larger a physician's experience the more he realizes that if he gives enough intravenous injections, even of the most carefully prepared isotonic saline and dextrose solutions, to enough different patients, sooner or later he will encounter a fever-chill reaction. The better the technique of preparing and administering all intravenous therapeutic agents, and making certain that the solutions are free of the usual pyrogenic substances, the less often will these reactions occur. In many hospitals, hundreds of injections of intravenous solutions have been carried out without a single reaction, and then one or several reactions have occurred.

It is well known that one cannot prevent the occurrence of nonhemolytic reactions after the administration of even the most carefully checked and proved, compatible blood transfusions. The general experience is that these reactions cannot be reduced to a level lower than about 3 per cent. This refers only to fever-chill reactions, or even more severe ones with urticaria, severe back or chest pains, and the like. If even milder reactions are counted, the total minimal percentage is between 6 and 7. However, even with full recognition of this, properly carried out blood transfusions are a well accepted, widely used therapeutic agent and are not infrequently life saving. These possibilities of reactions have merely caused every one to take infinite care in compatibility tests, in blood typing, and in careful transfusions when these are indicated.

The reactions referred to can be called nonspecific reactions. By this term it is meant that the reactions are not caused by specific agglutinogens or antibodies, such as A and B substances or by isohemolysins, isoagglutinins, anti Rh substances and so on. If a reaction is attributed to these agglutinogens or antibodies, data must be presented proving this. Aubert² has reached the same conclusion.

For example, if a reaction is considered caused by an incompatible transfusion of blood, this incompatibility must be demonstrated. If a reaction is termed a hemo-

lytic reaction, actual hemolysis must be demonstrated in the form either of hemoglobinemia or of hemoglobinuria. If the reaction is believed to be caused by the injection of incompatible agglutinins, then phenomena resulting from the incompatible agglutinins must be demonstrated in the patient or in the patient's blood, and not merely by *in vitro* tests with the patient's blood and a portion of the injected serum or plasma. If simple intravenous solutions are used, such as isotonic solution of sodium chloride, and a reaction occurs it is usually caused by pyrogenic substances in the solution or in the intravenous apparatus, and the same may be the cause of reactions following proved compatible blood transfusions or injections of plasma or serum.

There are two points which need discussion first.

1. What is the level of the titers of anti A and anti B agglutinins in routine pools of serum or plasma?
2. Is there any danger from incompatible isoagglutinins to a patient receiving intravenously a large amount of either this pooled material or high titered single specimens of serum or plasma?

The agglutinin titer of eleven mixed pools of serum was determined (table 1), no care being taken to adjust the relative number of samples from the different blood

TABLE 1—The Agglutinin Titer of Routine Pools of Normal Serums from All Four Blood Groups

groups in each pool.³ The agglutinin titer was determined by Davidsohn's method,⁴ which is a test tube technic, the end point being determined by observation under the low power microscope of the test tube placed on its side on the stage of the microscope. The result is recorded as the highest dilution in which clumps of three or more cells are seen, provided no clumping at all is observed in the next highest dilution. We have found this technic very accurate, and in duplicate tests it did not vary more than one dilution above or below the final reading. We believe it gives a reading of an even higher titer than the usual slide test read with the microscope.

The number of individual serums in each pool varied from ten to forty-nine. In all of the pools the agglutinin titer was low, the anti A agglutinin varying from 1:3 to 1:28, the anti B from 1:6 to 1:28. Since B and O serums in general are likely to have a higher titer of anti A agglutinins than the anti B agglutinins in A and O serums, it is interesting and important that the final levels of these two agglutinins in the mixed pools are approximately the same.

It has been demonstrated⁵ that there is definite neutralization or "suppression" of hemolysins and agglutinins when serums or plasmas of different blood groups are mixed together. This undoubtedly is caused through the neutralization of the antibodies by the dissolved A or B substances present in solution.

Dr D. G. Gemeroy has investigated this same problem, but even more extensively, and though his studies are in process of publication he has given permission to mention his results. His work was carried out at the Connaught Laboratories in collaboration with Prof. C. H. Best on pooled serums prepared by the Canadian Human Serum Project. Originally the blood types of serums added to each pool were in the same percentages as those in which these blood types occurred in the general population of Toronto. Each pool consisted of fifty serums with the following percentages of blood types in each pool: O 46 per cent, A 41 per cent, B 10 per cent, AB 3 per cent. The anti A agglutinin titers varied from 1:10 to 1:30, the anti B from 1:10 to 1:60. The technic was similar to the one we used.⁶

Since it was time consuming to select these serums in these proportions and much easier to pool the serums consecutively, the agglutinin titers were then determined first on several pools and later on many more, where fifty serums obtained consecutively were mixed regardless of blood types, although these blood types had been determined. It was found that, although there was some variation in the percentages of the blood types in the different pools, the agglutinin titers nevertheless remained at practically the same level as those in the pools originally studied.

These results seem to us extremely important, as they demonstrate that if pools are prepared of a sufficient number of serums or plasmas selected indiscriminately one can be certain that the agglutinin titers of these will be extremely low. Whether one should be required routinely to determine agglutinin titers in these final pools is a question that will be discussed later.

We next come to a discussion as to whether there is any evidence that the intravenous injection of plasma or serum low in agglutinin content can cause intravascular phenomena which are injurious to the patient, and whether injury to the patient can result if even large amounts of high titered plasma or serum are used.

We⁷ have investigated this problem to some extent, and Aubert and his co-workers have studied it even further.

Our study was carried out in three ways. 1. We repeated the work already referred to to determine the degree of suppression of agglutinins when pools are made of a number of samples of serum obtained from individuals belonging to the different blood groups. 2. We studied to what degree serum containing incompatible agglutinins could be diluted in whole citrated blood until the agglutinins are sufficiently diluted so that agglutination of cells does not occur. These mixtures were then stored in the ice box overnight and the supernatant serum was examined to find out whether

6. The serums were diluted in a similar manner in a series of marked test tubes. One drop of freshly prepared 1 per cent A or B suspensions was then added to each square of the serum dilutions on a large cell slide. The slides were then placed on a mechanical shaker and agitated for thirty minutes. The plates were then removed, the cells allowed to settle for ten minutes and agglutinin titers determined microscopically. The test was set up in duplicate in parallel rows on the plate.

or not the agglutinins had been completely absorbed. We injected intravenously therapeutic serums containing agglutinins incompatible with a patient's blood cells and followed the fate of the injected incompatible agglutinins in small samples of the patient's blood obtained immediately after administration of the serum and at subsequent intervals.

1 Our work was in agreement with the previous work that there is definite suppression of agglutinins when serum from the four blood groups are pooled. In none of these pools, as already mentioned, did we find an agglutinin titer higher than 1:28.

2 In table 2 there is found a protocol of a typical experiment in which agglutination was observed in vitro in a series of test tubes in which an incompatible serum was added to larger and larger amounts of citrated blood. In this experiment two serums were diluted with citrated A blood, one serum having an anti-A titer of 1:14 and the other 1:896.

It can be seen that even in a 1:1 mixture of the low titer serum and the blood there was no agglutination of the cells. In mixtures with the serum whose titer was 896 agglutination of cells was detectable in dilution as high as 1:80, that is, 1 part of serum with 79 parts of blood. However, agglutinins were completely removed in all dilutions from the supernatant plasma, which was examined the following day.

This experiment was repeated with three times concentrated serum prepared by making a pool consisting entirely of serum belonging to group O. The anti-A titer of this concentrated serum was 1:224, and the anti-B 1:112. In the mixtures of this serum with type A blood agglutination occurred in dilutions as high as 1:80, and with type B blood to dilutions as high as 1:20. The supernatant serum from these tests examined the next day showed not quite complete absorption of the agglutinins, since these were demonstrated in full strength serum against A cells from the mixture diluted 1:60 and against B cells from the mixture diluted 1:10.

One can see from the protocol given in table 2 that there was more complete absorption of agglutinins with a titer of 1:896 than with the three times concentrated serum whose agglutinin titer was considerably lower.

The foregoing findings will be referred to again in the discussion.

3 In 1938 Moureau, Bagaïries and Christiaens⁷ published apparently the first study of the fate of incompatible agglutinins injected intravenously. They transfused blood from universal donors with an unusually high anti-A titer ranging up to 1:1,024 into recipients belonging to types A or AB. Samples of blood were obtained from the recipients immediately after the transfusion and at later intervals and were examined for the presence of agglutinated clumps of cells. Moureau and his co-workers were unable to find agglutinated cells in any of these samples. We were not familiar with their work when we commenced ours.

We took advantage of the opportunity to carry out this study on patients who were given intravenous therapeutic or prophylactic injections of pooled convalescent scarlet fever or measles serums (human).⁸

The observations were made only on patients belonging to types A, B or AB. The serums were injected

into a vein in one arm, and samples were obtained with a fresh sterile syringe from a vein in the other arm immediately after the injection was completed and, in some instances, several hours later. Eight children and 7 adults received these serums. The amount injected varied from 50 to 100 cc. The titer of the incompatible agglutinins in the serums was as high as 1:896 in 1 instance, 1:448 in several other instances and considerably lower in others. The dilution of the serum injected in the total blood volume of the patient was calculated on the basis that the blood volume is one-tenth the weight of the individual. One child belonging

to type A, weighing 40 pounds (18 Kg), received 60 cc of convalescent scarlet fever serum with an anti-A agglutinin titer of 1:448. The calculated dilution of this amount of serum in the total blood of the recipient was 1:33 and in the plasma about 1:17. One adult belonging to type AB received 80 cc of convalescent scarlet fever serum with an anti-A agglutinin titer of 1:448 and anti-B of 1:56. This volume of serum was diluted 1:74 in the patient's blood. Several children received a quantity of serum which was a thirtieth or a fortieth of their blood volume, and in some of the adults the dilution of the serum was larger.

Nevertheless, in none of these patients did reactions occur, and none of the samples of blood obtained immediately after the serum was injected showed agglutination of red cells or hemoglobinemia, nor was

⁷ Moureau P, Bagaïries E, and Christiaens L. Existe-t-il des donneurs universels dangereux? Presse med 46:958 (June 18) 1938.

⁸ Dr I F Klein of the Willard Parker Hospital cooperated in this study.

it possible to demonstrate the presence of incompatible agglutinins in the serum obtained from these samples. These serums were all pooled serums even though the agglutinin titers of several were somewhat higher than the pooled serums already reported.

These negative laboratory findings correspond with the infrequency of reactions observed in an extensive experience obtained by many in New York, Chicago and other cities when scarlet fever convalescent serum (human) has been injected intravenously in the treatment of patients with scarlet fever. Some very sick children 4 to 6 years old have received 40 cc, and others 10 to 12 years old as much as 80 cc in one injection. Several children 14 to 15 years old have received single injections of 100 cc a day on eight to ten consecutive days. Only an occasional fever-chill reaction has been observed.

Whereas some of these reactions were unpleasant and disconcerting, none of them were followed by any harmful effect. They were all recovered from promptly, and most of the children went on to secure a beneficial therapeutic effect from the serum.

Aubert and his co-workers² have published two important investigations in this field. In their second study (the first investigation will be referred to later) they undertook to investigate whether there is a danger in transfusion of universal donor blood with a very high agglutinin titer into an individual belonging to type A, B or AB, for whom this agglutinin is incompatible. Instead of using high titered universal blood since the cellular elements complicate the study, they injected high titered incompatible serum, and apparently the serum that they used was that which they developed in their previous work. The titers of several of the serums used were 1:32, 1:128 and 1:512, others ranged from 1:1,024 through 1:16,384. Only several subjects received the low titered serums, most of the 16 receiving the high titered ones. Samples of blood were taken immediately after injection from a vein in the opposite arm, and these were studied under a microscope for agglutination of cells, called "agglutinates" by the investigators. Careful observations were made of clinical reactions including, of course, fever and chills, presence of hemoglobinemia or hemoglobinuria, serum bilirubin and the fall of the red cell count of the recipient.

None of the recipients receiving as much as 450 cc of serum of the titer less than 1:512 showed any agglutinates in the postinjection sample of blood. However, most of them who received from 20 to 500 cc of serum with titers of 1:512 or higher did show agglutinates in the postinjection sample, and in 2 of them in samples taken after three and a half hours. The serum bilirubin rose in many, and the red cell count fell quite definitely in many. Hemoglobinemia and hemoglobinuria occurred in several. Chills occurred three times, headaches and fever above 100 F nine times. "Five developed a syndrome, the most striking symptoms of which were moderate or severe aching pains across the small of the back, often radiating to the thighs, constricting sensations in the neck and chest, intestinal colic, and nausea."

They noted that several recipients of low titered and even agglutinin free serum had similar reactions, additional evidence that such reactions are not dependent on high titered incompatible agglutinins.

Figures from two of their tests are worth recording. A man belonging to type A, weighing 140 pounds

(63.5 Kg) received in twenty minutes 450 cc of serum with an anti A titer of 1:128. This was about one-seventeenth his total blood volume. Nevertheless he had no reaction, and no agglutinates were found in his blood. A woman belonging to type A, weighing 120 pounds (54 Kg), received in twenty-five minutes 500 cc of serum with an anti A titer of 2,048. This was about one-twelfth her total blood volume. The highest her temperature reached was 99.5 F and there were no subjective symptoms, but there were intravascular agglutinates present in large numbers, persisting for two hours. It is extremely interesting, as these investigators also note, that no detectable embolic phenomena whatever were caused by these agglutinates, some consisting of eight to ten red blood cells.

The only published study I have found of the intravenous injection of serum containing A or B substances besides that of Levine and State was the other study mentioned, carried out by Aubert and his co-workers. They injected intravenously from 100 to 350 cc of A or B serum secured from a single individual into ten normal type O recipients. The object of this study was to determine whether the intravenous administration of A or B substance would stimulate the recipient to produce a definite increase in the corresponding anti-agglutinin. In all the recipients a definite specific and sometimes nonspecific increase in agglutinins occurred, in several instances to a titer of 1:8,000 or 1:16,000. Although these recipients were very carefully followed there is no mention that any suffered from any reactions at all. Certainly no mention was made of any reactions that might be attributed to the injection of incompatible A or B agglutinogens.

One of their interesting observations is what they term the "inhibition index" of a serum. By this they mean the ability of a serum to reduce the titer of incompatible agglutinins in another serum.

They clearly indicate that the inhibiting substance is dissolved A or B agglutinin. They describe the inhibition index as follows: The index of a serum is 8 if it reduced the titer of an agglutinin from 1:128 to 1:16 and 2 if it reduced the titer from 1:64 to 1:32. The index, therefore, represents the number of times the titer has been reduced. They do not consider this an absolute figure but as an approximate guide of the amount of incompatible substance present.

This should prove a useful method for determining at least approximately whether A or B substances are present in any appreciable amount in pooled serum or plasma. This study should be made and is of importance, since the question has been raised as to whether incompatible A or B substance can cause specific, deleterious reactions when present in plasma or serum that is administered intravenously.

It is sufficiently important to quote in full the summary arrived at by these investigators:

The transfusion of conscious recipients of group A (12 cases) with considerable volumes of group O serum or plasma containing extremely potent anti A isoagglutinins did not produce any reaction which could be classed as dangerous. No evidence, therefore, was obtained that 'incompatible' isoagglutinins are responsible for severe or fatal hemolytic reactions.

In all these transfusions, however, there was some evidence of red cell destruction in the recipient, with the production of symptoms in some cases.

Group O blood with an agglutinin titer of 1:512 and over is not recommended for recipients of other groups in non-emergency transfusions designed to raise the red cell count.

The agglutinin present in the plasma of group A recipients is not an absolute protection against anti A agglutinins.

The isagglutinin content of serum and plasma pools prepared by the techniques used at the London Blood Supply Depots can safely be ignored [titres supplied]

COMMENT

It should be pointed out that several investigations have now demonstrated that when plasma or serum obtained from a sufficient number of individuals belonging to all four blood groups is pooled there is definite suppression of anti A and anti B agglutinins. The resultant titer of these might be anywhere from 1:6 to 1:60 but not any higher than this.

Type B serum with an anti A agglutinin titer of 1:896 showed agglutination in the test tube when this was mixed with citrated type A blood in a dilution of 79 parts of blood to 1 part of serum but not in higher dilutions. This demonstrated that *in vitro* even in a dilution of 1:80 agglutination of cells will occur. Nevertheless, Aubert and his co-workers found that, when a serum containing incompatible agglutinins to a titer of 1:2,048 was injected intravenously into a patient in the proportion of 1 part of serum to 12 parts of the entire blood volume, no reaction occurred and no intravascular agglutinates were formed.

Also in other studies described in the foregoing, when the fate of reasonably high titered agglutinins that had been injected intravenously was followed we found that the agglutinins disappeared almost immediately.

We believe that the evidence indicates that there are at least three mechanisms for neutralizing incompatible agglutinins that might be injected intravenously: 1. The agglutinins are suppressed to some extent by free agglutininogen in solution in the plasma. 2. Neutralization occurs by circulating cells, included in this must be the factor of the dilution of the injected agglutinins. 3. Since agglutinins are neutralized more readily when injected into a person's circulating blood than when added to blood in the test tube, there must be other agents to neutralize the incompatible agglutinins, such as the agglutininogens in fixed tissue cells. Just because plasma or serum will cause agglutination in the test tube is no proof that it also will cause agglutination when injected intravenously into a patient from whom the blood was obtained to carry out the test.

The evidence seems quite clear that therapeutic doses of pooled serum or plasma can be safely administered intravenously when indicated, regardless of the blood type of the recipient, provided the titer of the incompatible agglutinins is less than 1:512, and many times when the titer is even higher.

Evidence has been presented that both the anti A and anti B agglutinin titers of pooled plasma and serum are well below 512, probably in the neighborhood of 1:20 or 1:30 but never higher than 1:60.

In the case report of Polayes and Squillace the agglutinin titer of the pooled plasma injected intravenously was only 1:16 and, from the evidence presented here, could not possibly account for the reaction in the patient. There is no evidence in their report that this reaction was a hemolytic one. On the contrary, though a severe reaction, it had merely the characteristics of a nonspecific reaction, which at times is caused by the administration of simple intravenous solutions, compatible blood transfusions and the like.

The evidence presented by Levine and State that reactions are caused by the injection of A or B agglu-

tinogen is far from conclusive. The type of reactions which they describe are general types of reactions and have no elements that could be characterized as specific. Furthermore, they have not demonstrated that a specific reaction occurred in the patient's blood stream. The skin test reaction which they describe can be produced by many substances, and there are many substances present in blood plasma besides A and B agglutinogens which might conceivably cause skin reactions.

They have omitted one very important control. They have not injected A or B substances or plasma containing A or B substances into patients belonging to type AB who do not have anti A or anti B agglutinins in their blood. If the injection of incompatible A or B substances is as dangerous as they believe it to be, one would expect that Aubert, a very careful worker, would have noted reactions in his investigation when he injected large amounts of A and B serum into type O recipients.

Even if A or B plasma obtained from 1 individual might cause reactions because of A or B agglutinogens in solution, it does not follow at all that pooled plasma or serum will result in reactions for the same cause. Aubert's evidence suggests that the A and B substances are suppressed or neutralized in pooling, just as the agglutinins are. In fact, it is scarcely conceivable that A or B agglutinogens can be present free in pooled plasma or serum which certainly contain free agglutinins, even though of a low titer. It is, of course, important that an investigation of the neutralization of these agglutininogens in pooled plasma or serum must be carried out as soon as possible.

Even if it is demonstrated that plasma from 1 individual might have certain elements of danger under some circumstances, this is not at all relevant as far as the use of pooled plasma and serum is concerned.

It is fortunate that Aubert's evidence has called attention to the possible minor risks from the injection of large amounts of incompatible high titered agglutinins, but, as he himself concludes, and as my own evidence also indicates, reactions that might be caused by high titered incompatible agglutinins are not serious and the intravenous administration of pooled plasmas and serums containing low titered incompatible agglutinins are completely safe and without any danger to the patient receiving them.

Nevertheless it is important to investigate whether A and B agglutinogens are neutralized in the process of pooling, and it might be advisable to determine whether the titer of agglutinins in all pools of plasma or serum is not higher than 1:60.

This leads to the suggestion that it seems advisable to have a central authority decide on a standard technique for determining agglutinin titers, since the diversity of techniques used by various workers is so great that it is impossible to make any accurate comparison of their results.

CONCLUSION

The extensive clinical evidence and the data which have been analyzed here demonstrate that in pools of a sufficient number of samples of plasma or serum obtained from donors belonging to all four blood groups the titer of both anti A and anti B agglutinins is reduced to such a low level that no danger can result to patients from the injection intravenously of even large therapeutic doses of these pools.

VITAMINS FOR THE PREVENTION
OF COLDS

DONALD W COWAN, MD

HAROLD S DIEHL, MD

AND

A B BAKER, MD

MINNEAPOLIS

Repeated studies have shown that both animals and man have a decreased resistance to infections of various kinds when suffering from vitamin deficiencies. Apparently this may be true for each of the better known vitamins. On the other hand, it has not been shown by adequately controlled experiments that the addition of any of the vitamins to a reasonably adequate diet produces increased resistance to infections of the upper respiratory tract, the millions of dollars' worth of vitamin preparations which are sold each year for this alleged purpose notwithstanding.

Most of the studies of vitamins for the prevention of colds have been limited to vitamin A alone or to vitamins A and D as contained in cod liver oil. The experiments with vitamin A have resulted almost uniformly in negative results, while cod liver oil has been reported by a number of authors to reduce the severity and by some the frequency of colds. Most of the latter reports, however, are based on inadequately controlled studies.¹

Investigations of the use of multiple vitamins in the prevention of colds have been very few. Stone and her co-workers² reported that the daily administration of concentrates of vitamins A, B₁, B₂ and D were effective in reducing the incidence of infection of the upper respiratory tract in 11 students. These few subjects however, were in poor general physical condition, in addition to being very susceptible to colds, and the observations extended only over a period of three and one-half months.

Kuttner³ studied 108 rheumatic children in a domiciliary institution. All these children were on the regular institutional diet, but one half of them received each day, in addition to the regular diet, 15,000 U S P units of vitamin A, 1,870 U S P units of vitamin D, 2,000 international units of vitamin C, 1,000 international units of vitamin B₁, 480 Sherman-Bourquin units of vitamin B₂, 40 "rat day" units of vitamin B₆, approximately 40 growth units of "filtrate factor" and the equivalent of 50 Gm of whole liver in nicotinic acid or one of its derivatives. Both groups were observed

from January 1 to June 1, 1939 and from Dec 1, 1939 to May 1, 1940. The conclusion of the author was that this study did not present any evidence that the addition of these vitamins to an ordinary, well balanced diet reduced the incidence of infections of the upper respiratory tract.

OUTLINE OF STUDY

The present investigation concerns the value of large doses of vitamin C alone (1939-1940 series) and of large doses of mixed vitamins (1940-1941 series) in the prevention of colds. As in our previous cold prevention studies, the subjects were all students of the University of Minnesota who volunteered to participate in the study because they were particularly susceptible to colds.

Students applied for admission to the "Cold Prevention Group" soon after school started in the fall quarter. At this time a record was made of each applicant's recent history of acute infections of the upper part of the respiratory tract with particular attention to the number and severity of colds experienced during the previous two years, the type of these colds, their duration and like information. In order to exclude from the study persons whose difficulties seemed to be due primarily to chronic sinusitis or

allergic rhinitis, special attention was paid to the condition of the nose and throat and to symptoms suggestive of allergy. As in previous studies, the students were assigned alternately and without selection to an experimental and to a control group. The students in the control group were treated exactly like those in the experimental groups except that they received placebos instead of the vitamin preparations.

THE REPORTING OF COLDS

The students in all groups were instructed to report to the Health Service whenever a cold developed so that a special report card could be filled in by a physician indicating the type of cold, the symptoms and the like. In addition, all students were interviewed every three months in order to check the completeness of the reports filled out at the time of each respiratory infection.

During the second year of the study (1940-1941) a supplementary check on the accuracy of reporting was instituted. This consisted in having each student fill out and return to the Health Service each week the special report card shown in figure 1. This card is

kept on file in the Health Service (fig 2). At the end of the school year these various reports were summarized according to experimental and control groups.

DAILY USE OF LARGE DOSES OF VITAMIN C

At the beginning of the school year 1939-1940, 427 were enrolled in the "cold prevention group." One hundred and eighty-three of these were supplied with 100 mg tablets of synthetic ascorbic acid and were instructed to take 2 such tablets (200 mg) daily throughout the "cold season," a total of twenty-eight weeks. Fifty other students, also supplied with 100 mg tablets of ascorbic acid, were instructed to take 2 tablets (200 mg) daily for the first two weeks, then 1 tablet (100 mg) daily throughout the season unless and until an infection of the upper respiratory tract developed, in which case they were to take 5 tablets (500 mg) on each of the first two days of the cold,

TABLE 1—Vitamin C in the Prevention of Colds

after which the 100 mg daily dose was to be resumed. Since the results of these two subgroups were not significantly different, they are presented in table 1 as a single vitamin C group.

To serve as a control group 194 students were supplied with placebo tablets of the same size, shape,

appearance and taste as the ascorbic acid tablets. These students, of course, did not know that they were serving as controls. The instructions were to take 2 of these placebo tablets daily throughout the "cold season."

It will be noted that, while the students who took vitamin C throughout the "cold season" experienced only 1.9 colds per person annually during the study as compared with the reported 2.2 colds per person annually previous to the study, a reduction of 65.5 per cent the controls reported an average of 2.2 colds per person a year during the study as compared with 5.9 colds per person annually in previous years, a reduction nearly as great, namely 62.7 per cent. The actual difference between the two groups during the year of the study amounts to one third of a cold per person. Statistical analysis of the data reveals that a difference as large as this would arise only three or four times in a hundred through chance alone. One may therefore consider this as probably a significant difference, and vitamin C supplement to the diet may therefore be judged to give a slight advantage in reducing the number of colds experienced. However, one may well

Fig 3—Incidence of colds in three groups of students from Oct 20 1940 to April 20 1941. Broken line indicates group given 2 multiple vitamin capsules daily; dot and dash line indicates group given 1 multiple vitamin capsule plus added thiamine hydrochloride and nicotinic acid daily; and solid line indicates control group given 2 placebo capsules daily.

question the practical importance of such a difference. There are also slight differences in favor of the vitamin C group in regard to the percentage of students who had no colds of twenty-four or more hours' duration during the year of the study and in regard to the average number of days lost from school because of colds. On the other hand, those who took the vitamin C had, if anything, more complications such as bronchitis, otitis and sinusitis than did those in the control group.

MULTIPLE VITAMINS IN COLD PREVENTION

At the beginning of the school year 1940-1941 a total of 347 students were enrolled in the multiple vitamin study. Of this group only 264 cooperated throughout the year, which represents a smaller percentage than in most of our studies, possibly because of the increased demand made on the students during this year in the form of weekly report cards, special examinations of the nose and throat and the like. The results shown in figure 3 and table 2 are based only on those who cooperated throughout the "cold season."

At the beginning of the year 120 of these 347 students were instructed to take 2 capsules of multiple vitamins ("Hepicebrin") daily throughout the "cold season."

⁴ Stafford C I. The Common Cold. An Evaluation of an Oral Vaccine Based on a Controlled Study. *Journal Lancet* 60: 319 (July) 1940.

⁵ Both the ascorbic acid and the placebo tablets were furnished by Hoffmann-La Roche Inc., Nutley, N. J.

These provided a daily supplement of 20,000 U S P units of vitamin A, 12 mg of thiamine hydrochloride, 200 micrograms of riboflavin, 50 mg of ascorbic acid and 2000 U S P units of vitamin D. A second group of 107 students was given the following daily vitamin supplements: vitamin A 10,000 U S P units, thiamine hydrochloride 48.6 mg daily for the first week and 3.6 mg daily thereafter, riboflavin 100 micrograms, ascorbic acid 25 mg, vitamin D 1,000 U S P units and after January 1 nicotinic acid 50 mg daily. This dosage was obtained by the daily administration of 1 multiple vitamin capsule together with the thiamine hydrochloride and nicotinic acid already indicated.

The control group for the experiment consisted of 120 students who were furnished placebo capsules which

were indistinguishable from the multiple vitamin capsules.⁶ These were prescribed at the rate of 2 daily throughout the "cold season."

RESULTS WITH MULTIPLE VITAMINS

Table 2 and figure 3 present the results of this study. From table 2 it is apparent that there is no difference in the number of colds reported by the experimental and control groups. The same is true for the weekly occurrence of colds as shown in figure 3. The total number of colds reported by students in all groups was higher in this study than in most of our other experiments. This is in keeping with the general impression that the year 1940-1941 was characterized by an exceptionally high incidence of colds in the general school population.

6 The vitamins as well as the placebo capsules were furnished by Eli Lilly & Co., Indianapolis.

Table 2 also presents an attempt to evaluate the relative severity of the colds reported by the students in the various groups. Three sets of criteria were used in this analysis. The severity of colds as reported on the weekly cards was estimated in much the same manner as was utilized by Shibley and Spies⁷ and by Stafford.⁴ The occurrence of nasal discharge and obstruction with or without cough, sputum or sore throat lasting for more than one day but without aching, fever or confinement to bed was classified as a mild cold. The presence in addition of one of the recorded features of fever, aching or confinement to bed resulted in the classification moderately severe, if two of these features were present the cold was labeled severe, and if all three were present, that is if the student reported that he had fever, generalized aching and was confined to bed, the cold was classified as very severe.

In a further attempt to determine whether the medication modified the severity of the colds, the student was asked at the end of each cold he did experience to give an opinion as to how that particular cold compared with his previous colds (fig. 1).

An examination of table 2 does not reveal any evidence that the multiple vitamins reduced the severity of the colds. In fact, complications were more frequent among the students who got the vitamin supplements than among the control group. Furthermore, the average duration of each cold was the same for all three groups.

SUMMARY

This controlled study yields no indication that either large doses of vitamin C alone or large doses of vitamins A, B₁, B₂, C and D and nicotinic acid have any important effect on the number or severity of infections of the upper respiratory tract when administered to young adults who presumably are already on a reasonably adequate diet.

ABSTRACT OF DISCUSSION

DR. JOHN A. FERRELL, New York: May I inquire of the authors whether some of their study and control groups were known to have one or more vitamin deficiencies when the observations began? If not, what would be the rationale of administering vitamins to persons among whom no deficiencies had been determined with a view of influencing the incidence of colds due to viruses? With regard to the influenza viruses, the authorities in this field report that when resistance is built up against a specific virus the antibody titer for this virus is raised to a notable degree. Did you make any tests of your subjects relative to their antibody status for one or another of the viruses? The answers to these questions would be of real importance when testing the effectiveness of any therapeutic agent against a specific infection.

DR. JOSEPH S. LAWRENCE, Albany, N. Y.: Although the figures show practically no difference in the prevalence of colds between the two groups if I gathered correctly from the statistics, there was however, an appreciable diminution of colds among those examined as compared with the prevalence of colds among other students that winter. The students of both groups claimed also that they had had fewer colds than in the preceding winter. I wonder if the authors of the paper have an explanation for this apparent difference in incidence.

DR. HAYEN EMERSON, New York: This is a matter of the greatest importance to officers of the government concerned with the character of advertising claims that certain commercial preparations will stop and cure colds. The whole technique of

7 Shibley, G. S. and Spies, T. D. The Effect of Vitamin A on the Common Cold. J. A. M. A. 103: 2021 (Dec. 29) 1934.

testing colds is at stake, and this is a good example of a carefully controlled study. I hope other questions as pointed out by those that have been asked will be put to the authors. This is not an isolated undertaking in clinical research. Dr Diehl and his colleagues have made many efforts to unravel the epidemiology of colds and to produce some practical proof of prevention and of successful treatment.

DR DONALD W. COWAN, Minneapolis. In regard to the first question, we did no analyses to see whether or not the students were suffering from vitamin deficiency. We assumed that they were not, since most of them were on a reasonably adequate diet. We made no antibody studies either. We had no preconceived idea as to the value of vitamin therapy in the reduction of colds. We didn't know whether they would help or would not help. We merely used the vitamins because so many of them were being used by so many people that we thought a real controlled study was indicated to determine whether or not there might be something to the belief that persons taking large doses of expensive vitamins had fewer colds. There is, as far as I know, no rationale for it and we certainly were not able to demonstrate that the vitamins were of any value. In regard to the question asked by Dr Lawrence there is a remarkable decrease in the reported number of colds on the part of both the control subjects and the experimental subjects in all of our cold prevention studies. We are at a loss to explain this 60 to 65 per cent reduction that we find in persons who are taking injections of sterile saline solution when they are controlling an experiment with injected vaccine, or starch tablets when they are controlling some oral vaccine, or capsules of liquid petrolatum when they are acting as controls for vitamin concentrates. One thing that might enter into the remarkable reduction in the number of colds among students in the control group is the fact that when one is taking two or three pills every day or is given a shot in the arm once or twice a week because he is cold susceptible he is continually being reminded that he is trying to do something about his colds, and he might consciously or unconsciously practice better general hygiene, which might decrease the number of colds which he has. For example, at Minnesota students are often observed dashing from their rooming houses to the corner drug store at 20 below zero without hats or coats. I wonder whether they aren't more likely to put on a hat and coat when they are in the cold prevention group.

DR HAROLD S. DIEHL, Minneapolis. In further response to Dr Ferrell's question, the reason for making this study was not that we thought these students exhibited vitamin deficiencies but that the average population is buying millions of dollars worth of these vitamins every year, much of which is stimulated by advertising which suggests that vitamins will prevent colds. The question that we were attempting to answer was: Are vitamins of any value for the prevention of colds in a cross section of the population such as we get in a university? In a group of university students one would not expect to find much vitamin deficiency, and yet in a big state university, such as Minnesota, a large portion of our students are self-supporting, living in rooming houses and eating in restaurants. Observing cafeteria selections, we know their diets are not what we would recommend. Hence we can be certain that the economic level of these students and the type of diet they are getting is probably not as good as that of the average person who buys vitamin pills. Another point emphasized by this study, as well as by our previous studies on colds, is that if studies of this sort are to have any significance they must be done with a control group, and that control group must be treated in the same way as the experimental group. Results are not significant if this control group receives nothing. The control group must be given something which has the same psychological effect as the treatment received by the experimental group. Our studies show that placebos frequently give what appear to be excellent results. It is common for the control group to report a reduction from an average of five to about two colds a year. In fact, certain results reported by many persons who received placebos would serve as splendid testimonials for anything for the prevention of colds.

CARDIAC EFFICIENCY AND PROGNOSIS FOLLOWING RECOVERY FROM ACUTE CORONARY OCCLUSION

THE RESULTS OF VARIOUS FUNCTIONAL TESTS

COMMANDER ARTHUR M. MASTER

Medical Corps United States Naval Reserve

SIMON DACK, M.D.

AND

HARRY L. JAFFE, M.D.

NEW YORK

In previous reports we¹ presented detailed clinical observations of 202 patients with acute coronary occlusion followed for a period of one to seven years after discharge from the hospital. Particular attention was paid to the cardiac status as determined by symptoms and physical examination. It was found that at least one third of the patients were able to lead a fairly active life with little or no restriction of ordinary activities and one half were able to return to full or part time work.

This study represents the results of objective tests of cardiac function performed serially in these 202 patients now followed two to eight years. These tests were vital capacity, the "Master two step" exercise tolerance, teleoroentgenogram for the size and configuration of the heart, fluoroscopic and roentgenkymographic study of ventricular pulsation, ordinary electrocardiogram and electrocardiogram after the standard "two step" exercise. An attempt was made to correlate the results of the tests with the clinical symptoms, physical findings and subsequent course of the patient. By repetition of the tests at intervals of three to twelve months it was possible to determine approximately when each test returned to normal.

To evaluate the various tests, the patients were grouped according to the degree of recovery. This was based on the presence and severity of angina pectoris, dyspnea and weakness and the physical findings, such as heart size, heart sounds and rate, signs of heart failure and blood pressure. Recovery of 66 patients (33 per cent) was considered good, of 57 (28 per cent) fair and of 79 (39 per cent) poor.

VITAL CAPACITY

Peabody and Wentworth,² Pratt³ and subsequently other investigators⁴ demonstrated a close relationship between a decreased vital capacity and pulmonary congestion due to left ventricular failure. White and

McGinn⁵ reemphasized the value of the vital capacity as a measure of pulmonary congestion, particularly when repeated determinations were made on the same patient.

In a previous study⁶ of acute coronary occlusion, serial determinations of the vital capacity during the acute stage revealed a moderate to pronounced reduction (400 to 2,000 cc) in two fifths of 80 patients. With clinical improvement the vital capacity tended to rise progressively.

TABLE 1—Vital Capacity

Normal (3,000 cc or more)	72 (38%)
Slightly diminished (2,500 to 3,000 cc)	52 (27%)
Moderately diminished (2,000 to 2,500 cc)	49 (26%)
Considerably diminished (less than 2,000 cc)	16 (8.5%)
Not done	13
	202

The present follow-up study contains repeated vital capacity determinations on 189 patients (table 1). One third had a vital capacity of 2,500 cc or less representing a moderate to pronounced reduction from normal. A return to normal occurred generally during the first year after the attack and in more than half the patients within five months (table 7).

The small incidence of very low vital capacity (8.5 per cent) conforms with the infrequency of chronic heart failure and severe dyspnea in our series. As might be expected, the lowest vital capacity readings were encountered in the poor recovery group (table 8), but even in this group the vital capacity not infrequently was normal when heart failure was absent, the disability being due to angina pectoris. Therefore a normal vital capacity does not exclude the presence of cardiac disability, although a significant degree of heart failure is unlikely.

EXERCISE TOLERANCE TEST

Numerous types of exercise tolerance tests have been advocated for the determination of cardiac function. While no test is wholly free from criticism, we have found the Master two step test⁷ simple and reliable. The test is based on the effect on the pulse rate and blood pressure of walking up and down two steps, each

TABLE 2—Two Step Exercise Tolerance Test

This test is particularly suitable for patients with coronary artery disease and angina pectoris because of the short duration and nonstrenuous nature of the exercise and because the amount of exercise necessary to produce symptoms of coronary insufficiency, such as pain, dyspnea and fatigue, can be determined. This is of great aid in studying the progress of the patient⁸ and the degree of myocardial reserve. In recent years we have combined the two step test with the electrocardiogram, recording the latter before and immediately after exercise.⁹

The exercise tolerance was performed serially by 178 patients (table 2). The response of the pulse rate and blood pressure was normal in 18 per cent of the patients and distinctly abnormal in almost two thirds. The majority of the latter complained of pain, dyspnea or undue fatigue during or immediately after the test.

The exercise tolerance test usually did not return to normal until one or two years after the attack (table 7). In a few cases the return to normal occurred as early as two to five months after the attack and in a small group only after three or four years. Return of the exercise tolerance to normal was usually associated with a good recovery from the attack. Although 42 per cent of the good recovery

group responded abnormally to this test, the frequency of an abnormal response was much higher (86 per cent) in the poor recovery group (table 8).

HEART SIZE (TELEOROLOGENOGRAFI)

The relation of coronary sclerosis, coronary occlusion and myocardial infarction to cardiac enlargement has been the subject of numerous clinical and pathologic studies. Several investigators¹⁰ believe that coronary sclerosis or myocardial infarction is often the sole factor in the development of cardiac enlargement. The preponderant opinion,¹¹ however, is that coronary disease or myocardial infarction as such does not lead to ventricular enlargement unless hypertension has been present or congestive heart failure intervenes. Our observations¹² during the acute attack have shown that approximately three fifths of cases give evidence of cardiac enlargement, particularly of the left ventricle.

¹² Master A. M., Dack Simon and Jaffe H. L. Age, Sex and Hypertension in Myocardial Infarction Due to Coronary Occlusion. *Arch. Int. Med.* 64: 767, 786 (Oct.) 1939. Master Dack and Jaffe.

The vast majority of these are hypertensive or give a history of previous hypertension.

Similar findings have been reported during the follow-up period. In a radiologic study of 20 cases of coronary occlusion with normal heart size followed one half to ten years, Horne and Weiss¹³ found no increase in heart size, suggesting that enlargement does not occur unless hypertension or heart failure has been present. Palmer¹⁴ found distinct cardiac enlargement radiographically in 64 per cent of 200 patients who had survived a coronary occlusion at least three months and considered hypertension the causative factor in four fifths.

In the present study serial telorontgenograms were obtained in 196 cases (table 3). About one half had definite enlargement, graded 1 to 4 plus, in one third the heart size was within normal limits and in the remainder left ventricular hypertrophy with little or no gross enlargement of the heart was present.

Fig 1—Cinerontgenograms (movies of fluoroscopic screen) of a man aged 44 who sustained a coronary occlusion two months before. *A* diastole. *B* systole. *A* localized expansion of the midportion of the left ventricle is observed during systole (arrow). This is characteristic of previous infarction. The electrocardiogram which showed inversion of T_2 and T_3 during the acute attack returned to normal within two months at the time of this fluoroscopic examination.

It has previously been pointed out¹⁵ that hypertension (150 mm or more systolic and 90 mm or more diastolic) had been known to exist in 60.4 per cent of the patients prior to the acute attack of coronary occlusion. During the follow-up period the incidence of hypertension was only 37.8 per cent, indicating that in over one third of hypertensive patients the blood pressure failed to regain a hypertensive level.

Cardiac enlargement was observed in only one third of the good recovery group but in over two thirds of

those making a poor recovery (table 8). Thus, recovery of cardiac function is more apt to be complete when the heart size is normal, yet a severe degree of coronary disease may exist without cardiac enlargement. In such a case disability is usually due to angina pectoris rather than to heart failure.

VENTRICULAR PULSATIONS (FLUOROSCOPY AND ROENTGENOGRAM)

Myocardial infarction following acute coronary occlusion can be detected fluoroscopically in half the cases by the presence of localized systolic expansion or reversal of pulsation of the left ventricular border.¹⁶ Instead of a uniform contraction of the left ventricle a lateral movement is observed during systole, usually in its lower half (fig 1). Furthermore, 20 per cent of cases exhibit other abnormalities of contraction, such as localized absence or diminution of left ventricular pulsation. In the remaining cases the ventricular pulsations remain normal. These fluoroscopic observations have been confirmed by roentgenkymographic studies.¹⁷

In the present series repeated observations of the ventricular pulsations were made fluoroscopically or kymographically on 176 patients (table 4). In 58 per cent the findings were characteristic of infarction that is, complete or partial systolic expansion was present, nonspecific changes, i.e. absent or diminished pulsations, were present in 25 per cent. Therefore normal pulsations existed in only 30 cases, or 17 per cent. As

examinations, usually during the first year and sometimes only after several years (table 7)

The presence of abnormal ventricular contraction did not preclude a good recovery from the acute attack. Thus an abnormal pulsation was observed in 70 per cent of the patients whose clinical recovery was classed as good. Nevertheless the ventricular pulsations are significant in the prognosis, for the incidence of abnormal pulsations was far greater in the poor recovery group, namely 94 per cent (table 8). In general a patient with normal myocardial contractions makes a good clinical recovery despite the persistence of other abnormal tests. This suggests that normal ventricular contraction following coronary occlusion is associated with a small myocardial infarct or a well healed scar.¹⁹

A study of ventricular pulsation following coronary occlusion is of diagnostic as well as prognostic value, since systolic expansion may be the only residual pathognomonic sign of previous infarction.²⁰ This was emphasized in a previous study²⁰ in which it was found that, although 44 patients presented electrocardiograms

It has been demonstrated that the characteristic Q_1Q_2 , T_1T_2 pattern of anterior infarction or the Q_3Q_4 , T_3T_4 pattern of posterior infarction develops in the great majority of cases in which serial tracings are obtained and that anterior and posterior infarctions occur with almost equal frequency.²¹ In a smaller group of cases the findings of both anterior and posterior infarction are observed and the electrocardiographic pattern may be less characteristic than in the former groups. Rarely the electrocardiogram remains normal in coronary occlusion or shows atypical changes, even in serial records. The observations made on the electrocardiogram during the years following recovery from the attack have not been detailed but it is known that good recovery may take place and yet T wave inversions persist.² Marvin²¹ observed that the persistence of T wave inversion following recovery did not significantly influence prognosis, since he found that inverted T waves persisted among several patients who were leading active lives, and, on the other hand, the return of the T waves to normal occurred among several patients who subsequently developed severe angina pectoris or heart failure. Levine and Rosenbaum²² noted that the electrocardiographic pattern, whether that of anterior or that of posterior infarction, did not affect length of survival or frequency and severity of subsequent angina pectoris. Following anterior infarction subsequent heart failure, however, seemed to be more common and restriction of physical activity greater. This was in accord with previous observations of Wood and his associates.²³

The electrocardiographic findings in serial records obtained in our series of 202 cases are summarized in table 5. The electrocardiogram returned completely to normal in 28 cases (fig 2) and almost to normal in 15 others. Thus the electrocardiogram returned practically to normal in more than one fifth of the cases, illustrating the fact that the absence of typical electrocardiographic changes does not exclude previous coronary occlusion.²⁰ The electrocardiogram returned to normal in a variable interval ranging from less than one month to four years. The majority returned to normal within one year (table 7). In 33 cases the electrocardiogram was abnormal but the typical pattern of myocardial infarction had been lost, 15 of these were of the "hypertensive" type seen in left ventricular enlargement and strain, and in 7 intraventricular block masked the signs of previous infarction.

Changes that were characteristic or suggestive of old infarction persisted in the remaining 126 cases. In 70 the pattern suggested anterior infarction, in 27 posterior infarction and in 29 combined anterior and posterior infarction. Even in these groups a regression

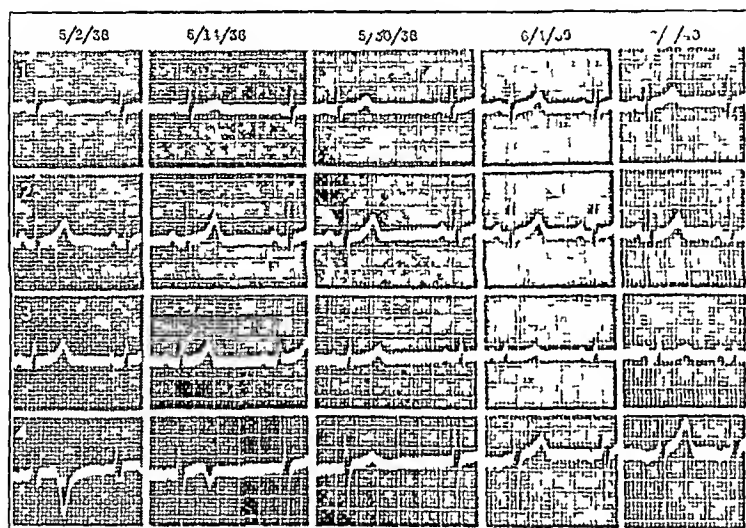

Fig 2—Serial electrocardiograms of a man aged 52 who sustained an acute coronary occlusion April 25 1938. Partial inversion of T_1 and deep inversion of T_2 indicate anterior wall infarction. The changes are transient. The record five weeks after the attack and subsequent records are normal. Clinical recovery was excellent. Symptoms were absent and all the functional tests became normal. The patient returned to regular full time work.

which had returned to normal or almost normal the fluoroscopic or kymographic examination revealed systolic expansion in a majority of them. Similar observations were made in the present series (fig 1). The ventricular pulsations may be helpful not only when the electrocardiogram has returned to normal but also when it is abnormal but has lost the typical appearance of previous infarction.

ELECTROCARDIOGRAM

In recent years the various electrocardiographic changes occurring during the acute and subacute stages of coronary occlusion have been thoroughly studied.²¹

26 Wood F C Bellet Samuel McMillan T M and Wolferth C C. Electrocardiographic Study of Coronary Occlusion. Further Observations on the Use of Chest Leads. *Arch Int Med* 52: 752-784 (Nov.) 1933.

of the abnormalities often occurred. In many cases a T wave which had been abnormal in two or more leads remained abnormal in only one lead. Not infrequently all the T waves returned to normal and only small or deep Q waves persisted (fig 3). Thus, in the anterior infarction group 4 cases presented only a deep Q₁ and Q₂ and in 5 cases all the changes disappeared except for a persistent deep Q₁, in 2 cases the standard leads returned entirely to normal but the precordial lead still presented the Q₁ T₁ pattern. Similarly in 1 case of the posterior infarction group all the changes returned to normal except a persistent deep Q₃ (fig 3), while in 2 cases of the anterior-posterior infarction group all the T waves became normal but the Q waves persisted in the standard leads.

The electrocardiogram became normal in 35 per cent of the good recovery group and in only 3 per cent of the poor recovery group (table 8). Hence return of the electrocardiogram to normal or almost normal was generally, although not invariably, associated with a good prognosis (fig 2). Furthermore, in the cases mentioned in which the T waves returned to normal and only deep Q waves persisted, a good or fair recovery was the rule. On the other hand, persistence of the characteristic electrocardiographic changes was not necessarily a bad prognostic sign, since this was true of the majority of patients making a good recovery. In our experience, not only is the location of the infarct of little importance with regard to severity and mortality rate of the acute attacks,⁶ but it also does not appreciably affect the clinical course during the follow-up period. A good recovery occurred in 33 per cent of patients with a persistent anterior infarction pattern and in 37 per cent of those with signs of a posterior lesion. However, the incidence of good recovery dropped to 22 per cent when signs of both existed. This can be attributed to the fact that the acute infarct was of larger extent or that two separate infarcts occurred. Good recovery was also uncommon, occurring in only 13 per cent in the group of cases in which the electrocardiograms remained abnormal, although not characteristic of previous infarction, including those with a hypertensive pattern or intraventricular block.

ELECTROCARDIOGRAM AFTER STANDARD EXERCISE

In recent years changes in the electrocardiogram following exercise have been studied in patients with chronic coronary disease.²⁷ Alterations may be produced similar to those observed during spontaneous attacks of angina pectoris, following anoxemia and in coronary insufficiency. They consist of transitory depression of the RS-T segment with or without lowering or inversion of the T waves. The test is often of great diagnostic value, particularly when the control electrocardiogram is normal or shows only minimal changes. We⁹ have modified the test by using the two step exercise and by standardizing the amount of exercise performed on the basis of the same sex, age and

weight tables used in the two step exercise tolerance test previously described.²³ In fact, the two tests, the ordinary exercise tolerance test and the electrocardiogram after exercise, can be performed simultaneously.²⁸ A positive result consists in the depression of the RS-T segment of more than 0.5 mm below the PR interval or the flattening or the inversion of the T wave in one or more leads or a combination of these findings (fig 4).

Electrocardiograms following standard exercise were obtained of 57 patients (table 6). For purpose of analysis they were divided into two groups 18 whose electrocardiogram had returned to normal or almost normal and 39 whose electrocardiogram had remained abnormal. In the former group the test was positive in 5 (38 per cent), in the latter group in 24 (62 per cent). The test of 2 patients of each group was negative after standard exercise, but it became abnormal with double the standard amount of exercise.

In 1 of the 5 cases with normal control electrocardiograms and abnormal changes following standard exer-

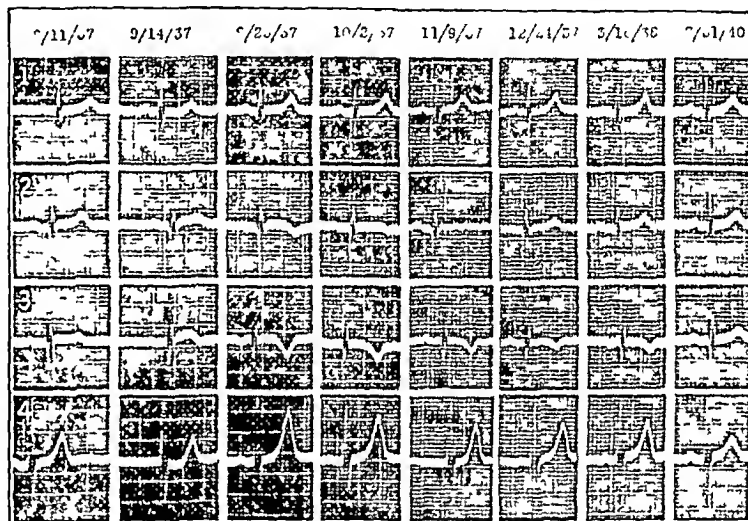

Fig 3—Serial electrocardiograms of a man aged 38 who sustained an acute coronary occlusion Sept 10 1937. The deep Q and Q₃ elevated RS-T in leads 2 and 3 and depressed RS-T in lead 4 progressing to inverted T and T₃ and tall T₁ are characteristic of posterior wall infarction. The T waves gradually returned to normal. Three years after the attack the record is normal except for a persistent Q₃. Clinical recovery was good the functional tests became normal. Activities were only slightly restricted and the patient returned to light work.

cise the test presented the only objective evidence of coronary insufficiency. All the other examinations in this case were negative despite the presence of a moderately severe anginal syndrome.

A negative electrocardiographic response to standard exercise was generally associated with a good clinical recovery, a normal test being obtained in three fifths of the good recovery group and in only one fifth of the poor recovery group (table 8). It must be remembered, however that in the latter group the control electrocardiogram was usually abnormal.

Summarizing our electrocardiographic findings it is apparent that return of the electrocardiogram to normal following coronary occlusion is associated with good cardiac function. This is borne out by the fact that of the 18 cases with a normal control electrocardiogram 13 showed a normal response in the electrocardiogram to exercise and in 12 the ordinary exercise tolerance

(determined by pulse rate and blood pressure response) was also normal. On the other hand, the majority of the cases showing coronary insufficiency in the electrocardiogram after exercise had a reduced exercise tolerance (fig. 4).

RELATION OF FUNCTIONAL TESTS TO CLINICAL COURSE

We have already stressed the prognostic importance of the various objective tests utilized in this study. We have shown that the incidence of abnormal findings was distinctly greater among patients who made a poor or incomplete recovery than among those whose recovery was good (table 8). The converse of this observation also was true, that is, the probability of a good recovery was much greater for those patients whose objective tests remained or returned to normal. This applied particularly to the exercise tolerance test, ventricular pulsations and electrocardiogram. In fact, if one or more of these three examinations remain or return to normal following the acute attack recovery is good with

expansion of the left ventricular contour was observed fluoroscopically, the electrocardiographic pattern of previous infarction persisted, the exercise tolerance test was distinctly below normal and the vital capacity was reduced, particularly if left heart failure was present.

The relation of the functional tests to clinical recovery was studied also by correlating the results of these tests with the presence or absence of angina pectoris and dyspnea, the two most common causes of disability following recovery from coronary occlusion. The results are presented in table 9. It is seen that in the group of patients who had no significant angina or dyspnea there was a lower incidence of abnormal tests.

Of special interest is a group of 6 patients, in whom all the objective tests actually became normal. The findings in this small group emphasize the point that an attack of acute coronary occlusion, if not very severe, may be followed by complete functional and anatomic recovery, as far as can be clinically determined (fig. 2). In the remaining 60 patients who made a good clinical recovery at least one of the tests remained abnormal, although the patients returned to normal activity and were able to work.

Fig. 4—Electrocardiogram after the standard two step exercise tolerance test in a man aged 57 who sustained an acute coronary occlusion with anterior infarction seven years before. Control is normal except for left axis deviation. Immediately after twenty one climbs the RST segment becomes depressed in leads 1, 2 and 4. Three minutes after exercise T₁ is low and T₄ diphasic. The record returns to normal within five minutes. These changes indicate transient coronary insufficiency induced by exercise. Although the electrocardiogram had returned to normal following the occlusion the patient suffered from moderate angina pectoris and was unable to work. Exercise tolerance and ventricular pulsations remained abnormal. The patient died suddenly following another coronary occlusion four months after this test.

very rare exceptions. The same general rule can be applied to the electrocardiogram after standard exercise, but the number of exceptions is slightly greater. It is not true of the vital capacity and heart size for, as we have shown, these may be normal despite a poor clinical recovery. Nevertheless, the frequency of a normal vital capacity or cardiac size fell proportionately with the

RELATION OF FUNCTIONAL TESTS TO FUTURE ATTACKS

The results of the tests differed widely in the patients who subsequently sustained another attack of acute coronary occlusion or developed acute congestive heart failure from those in whom another attack did not occur (table 10). The results of each test were abnormal more frequently in the former group. In fact, in those who had another attack the ventricular pulsations and electrocardiogram were almost universally abnormal and an enlarged heart and diminished exercise tolerance were present in the great majority. In the presence of a normal electrocardiogram or ventricular pulsation a subsequent attack of either coronary occlusion or heart failure or subsequent death was exceedingly rare.

SUMMARY

1 Cardiac efficiency was studied by various function tests performed serially on 202 patients, who were observed for two to eight years following recovery from acute coronary occlusion. The results were evaluated from a prognostic point of view.

2 Recovery from acute coronary occlusion was found to be good or complete in over one third of the patients, i. e., they had no symptoms of diminished cardiac reserve or routine activity. One half were able to return to work, usually full time, and cardiac reserve, as measured by function tests, was normal or only slightly abnormal.

3 A persistent reduction in vital capacity was rare in the good recovery group but common in those whose recovery was poor. However, the vital capacity not infrequently was normal in the presence of severe angina pectoris. A reduction below 2,000 cc was generally found only among patients who were in congestive heart failure.

4 The two step exercise tolerance test, a simple nonstrenuous test of cardiac function, became normal in 18 per cent and remained distinctly abnormal in two thirds of the patients. Return to normal usually

degree of disability of the patient. In a general way it may be stated that among the patients whose recovery was poor and whose functional capacity was much restricted the heart was enlarged, localized systolic

occurred one or two years after the attack and was associated with a good clinical recovery and decreased incidence of subsequent attacks.

5 The telorontgenogram revealed definite cardiac enlargement in half of the patients, and the majority of these were hypertensive. As a general rule chronic coronary sclerosis or coronary occlusion did not produce cardiac enlargement unless hypertension or heart failure was present. Although a severe degree of coronary disease may exist without cardiac enlargement, clinical recovery was more complete and subsequent attacks were less common when the heart size was normal, emphasizing the relation between heart size and cardiac function. Cardiac enlargement was always permanent.

6 A systolic expansion of the left ventricle, pathognomonic of previous infarction, was observed fluoroscopically or roentgenkymographically in nearly three fifths of the patients and localized absence or diminution of pulsation in 25 per cent. With few exceptions these abnormalities were permanent. Although an abnormal ventricular pulsation did not preclude a good recovery from the attack, it was almost universal in those whose recovery was poor. Not infrequently it was the only remaining sign of previous infarction being observed in the majority of patients whose electrocardiogram returned to normal. The patients with normal pulsations usually recovered completely and rarely sustained another attack.

7 The electrocardiogram returned to normal or almost normal in 21 per cent of the patients, usually within one year after the attack. The great majority of these made a good recovery, as well as those whose T waves became normal although the Q waves persisted. However, the persistence of the findings char-

(depression of RS-T or inversion of T wave) in 5 of 18 patients whose control record was normal and in 24 of 39 patients with abnormal electrocardiograms. A negative test was associated with a good recovery and good cardiac function.

9 The presence of a normal two step exercise tolerance test, normal ventricular pulsation or a normal electrocardiogram following coronary occlusion was usually accompanied by complete clinical recovery. Not only were significant angina pectoris and dyspnea uncommon when the foregoing tests became normal but a subsequent attack of either coronary occlusion or heart failure was rare. In those whose recovery was poor there was nearly always objective evidence of disability.

ABSTRACT OF DISCUSSION

DR CARY EGGLESTON, New York. On the basis of clinical experience and a recognition of the essential nature of the damage usually caused in myocardial infarction, one would be inclined to suspect a priori that no single objective test could be expected to yield results of significant value in prognosis as to degree of recovery of cardiac function. This a priori judgment appears to be confirmed by the results recorded in the paper of Drs. Master, Dack and Jaffe, although this does not impair the great value inherent in their study. Their results show that, on clinical judgment alone and without the application of any test, one third of the patients made a good recovery, 40 per cent a poor recovery and nearly 30 per cent a recovery intermediate between these two. When an effort was made to utilize one of the simplest of all measures of cardiac function, namely the vital capacity, the results obtained scarcely justified the time spent except in the small group of cases in which infarction is followed by congestive failure. This result, I think, was to have been anticipated, since lasting disability following infarction generally rests on the persistence of the development of angina pectoris as the limiting factor to the patient's activities. The second test applied, that of exercise tolerance, similarly gave results in fairly close conformity to those which were to be expected, that is, it confirmed the experience just mentioned, that where there is subsequent limitation of cardiac function it is generally due to the development or the persistence of the manifestations of angina pectoris. The authors have recognized these facts. My comments are not intended in any way to minimize the importance of this study. My criticisms are made to point out what appears to be the

characteristic of previous infarction, which was observed in almost two thirds of the patients, was not necessarily a bad prognostic sign. The location of the infarct, i.e., whether anterior or posterior, did not affect the clinical course. However, when infarction of both surfaces had occurred the prognosis was worse.

8 The electrocardiogram after the standard two step exercise revealed signs of coronary insufficiency

most important conclusion to be drawn from this study, namely, that while several tests may be employed for judgment of the degree of recovery of cardiac functional integrity after infarction, the results of such tests scarcely yield enough, when compared to clinical experience and good clinical judgment, to make the expenditure of time and labor worth while. I feel skeptical about the ability of any tests, alone or in combination, to provide a trustworthy foundation for prediction as to the probability of the patient's suffering a subsequent infarction. I remain to be convinced that that is true in a large series of cases—and 200 is not very large in a condition so common and diverse in its course as myocardial infarction. There is a field in which these tests may have much application, namely, in the solution of medicolegal problems based on the determination of the degree of restoration of heart function, for they certainly are capable of yielding objective data which can well be of more or less determinative value to present to a court.

DR HOWARD B. SPRAGUE, Newport, R. I. The fact stated that 40 per cent of patients who suffer from myocardial infarction return to fairly active lives is very encouraging. It shows how far we have come from the time when the diagnosis of coronary occlusion was considered essentially an immediate death sentence. It was stated that about half of the patients had cardiac enlargement and that about half had abnormal ventricular pulsations. I should like to know whether this half of the patients who had the big hearts were the half who had the abnormal ventricular pulsations. When I see cardiac enlargement following myocardial infarction under the fluoroscope I am influenced to discover that there are abnormal ventricular pulsations and do not so frequently see such a beautiful demonstration of reversal of pulsations as was shown on the screen. As far as the electrocardiogram is concerned, I agree as has been shown before, the failure of the electrocardiogram to return to normal does not mean that the patients will have a poor prognosis. I have the feeling that the rapidity with which the electrocardiogram during the acute stage defines itself as of the anterior-posterior type and the speed at which the ST displacements return to normal are the important immediate prognostic elements. The point is important that the patient will largely have recovered as much as he will in a year as far as all these objective tests are concerned. That is my clinical opinion. Perhaps the best and the simplest way to discover whether or not a patient has made a recovery from myocardial infarction is first to find out how big his heart is and, second, whether he has shortness of breath or signs of angina pectoris when he gets about.

DR ARTHUR M. MASTER, Bethesda, Md. There is always a disinclination to learn new methods or new tests and that is the situation in Dr Eggleston's case. In a long experience in clinical practice and in research we have found functional tests valuable and have used them constantly. The military forces too have found them indispensable. To learn the value of function tests one necessarily assays them on patients who are in an obviously poor or good clinical condition. Once the value of the tests is thus proved they are performed on patients in whom the diagnosis or prognosis is in question. The tests are as useful in a prognostic sense as in a diagnostic. The tests described are simple and are objective for the most part. This makes them particularly valuable since one does not always obtain the whole truth from the patient. He may be hyposensitive or his history may be colored by insurance or compensation angles. With regard to enlargement of the heart and the ventricular pulsations, one does see a higher incidence of systolic expansions or reversals on fluoroscopy in large hearts. We have published our figures. However, one will just as definitely see the systolic expansion in small hearts and often more clearly since there is more lung background. As a matter of fact my very first observation occurred in 1933 on a woman with a very small heart. As to the facilities for observing these abnormal cardiac pulsations on the fluoroscope, one should have a good Patterson B screen. However, it is preferable, but not necessary, to have some one actually demonstrate the fluoroscopic changes we have described. It is good to possess a healthy skepticism but we overcame this four or five years ago. We proved our case by actual demonstration. Patients were sent

into the dark room and we were asked to pick out those with systolic expansions, i. e. patients who had had coronary occlusion previously. We were able to do it. I might add that after a little training my pharmacist and corpsmen at the National Naval Medical Center in Bethesda make the fluoroscopic diagnosis of coronary occlusion without difficulty.

CHRONIC MOUNTAIN SICKNESS

ALBERTO HURTADO, M.D.

LIMA, PERU

The resident of high altitudes, native or newcomer, lives in a condition of chronic anoxia, as shown by the lowering of the arterial oxygen saturation.¹ The existence of a complete adaptation to this condition, when moderate or severe in degree, and the level of altitude at which the required compensatory processes cease to be within physiologic limits still remain as problems to be elucidated.

In 1928 Monge² indicated that an accentuation of the polycythemia commonly found in residents of high altitudes constitutes a main alteration among the various conditions which characterize the loss of tolerance to a low barometric pressure environment. In subsequent writings Monge³ described the symptoms and signs which accompany the hematologic disorder to which the names of chronic mountain sickness, high altitude erythremia and Monge's disease have been given. The disappearance of the polycythemia on descent to a lower altitude or to sea level is, according to Monge, a basic aspect of the condition.

The present communication concerns observations made in 8 of these cases in an effort to obtain some information regarding the underlying etiologic mechanism or mechanisms. The patients were men of Indian race, born and living at altitudes between 4,000 and 4,500 meters (13,120 to 14,760 feet) and of an age ranging between 24 and 44 years. Six of the men were studied at high altitudes and two of them immediately after arrival at sea level. None of them had previously worked in mines or foundries or in any other dusty occupation.⁴ Among their most common symptoms may be cited headache, dizziness, ringing in the ears, vague pain in the extremities, cough, shortness of breath on exertion, palpitation, moderate hemoptysis, epistaxis and gastric distress with a feeling of indigestion. Cyanosis, dilated superficial vessels and a moderate to a conspicuous clubbing of the fingers and toes were

4 The hematologic and other alterations found in cases of pulmonary mononucleosis (silicosis) which have been interpreted as being due in part to an associated chronic mountain sickness (Monge's disease) are, in my opinion, solely related to the increased arterial unsaturation caused by the pulmonary changes present in the former disease and are similar in nature to those observed at sea level in cases which show some degree of anoxemia. The improvement or disappearance of the symptoms on descent to a lower altitude is a consequence of the higher arterial saturation under these circumstances. Oxygen at the normal partial pressure of sea level may be able to diffuse better through a thick alveolar membrane less permeable when the gas is at reduced tension at high altitudes.

prominent features in all of them. Liver, spleen and glands were not palpable. The blood Kahn reaction was positive in case 5. The physical characteristics corresponded to their Indian race (average height 1.57 meters, average weight 55.4 Kg.), the nutritional condition was normal in every case.

The results obtained in the various hematologic observations are given in tables 1 and 3 and are partly presented, graphically, in figure 1.

In another communication⁵ the hematologic characteristics observed in healthy native residents at different altitudes were discussed. The comparison of those results with the ones found in these cases reveals a considerable rise in the red blood cells, hemoglobin, hematocrit reading, viscosity and bilirubin in the men showing signs and symptoms of chronic mountain sickness. In 2 cases the circulating reticulocytes were

Fig 1—Hematologic observations in 8 cases of chronic mountain sickness (at an altitude of about 4,450 meters 14,900 feet). Findings compared with mean values observed in healthy residents at that altitude (upper horizontal interrupted lines).

abnormally elevated. No significant changes were observed in the morphologic characteristics of the circulating red cells with the exception of a moderate lowering of the corpuscular hemoglobin concentration in 3 cases. The blood volume determinations showed a decided increase in the circulating red cell volume and hemoglobin and a decrease in the plasma volume. The total blood volume was elevated. These findings correspond to an absolute polycythemia of the type of polycythemic hypervolemia, in agreement with the original observation⁶ made in 1937. The leukocytic concentration and differential count were similar to those found in healthy residents.

⁵ Hurtado Alberto. The Influence of Anoxemia on the Hemopoietic Activity, read in the General Scientific Meetings at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 8, 1942.

⁶ Hurtado A. Aspectos Fisiológicos y Patológicos de la Vida en la Altura. Editorial Rimac, Lima, 1937.

Figures 2 and 3 correspond to the blood volume determinations made on some of the subjects after they had been taken down to sea level. It may be observed that in all cases, with the exception of 1 observed thirty days after arrival, a considerable decrease occurred in the circulating blood volume brought about by the low-

Fig 2—Circulating blood volume and hemoglobin (expressed in cubic centimeters and grams per kilogram of body weight) in cases of chronic mountain sickness studied at high altitudes (HA) and after descent to sea level (SL).

ering of the red cell volume. There was a moderate increase in the plasma volume. The series of determinations made in case 5 (fig 3) have an interesting aspect on account of the prolonged time the man was under observation, both at high altitudes and at sea level. A rise in the plasma volume paralleled the decrease in the cell volume when this subject was living at sea level. I have observed this phenomenon in some other cases (unpublished observations) during the first weeks of residence at sea level.

Fig 3—Circulating blood volume and hemoglobin (expressed in cubic centimeters and grams per kilogram of body weight) in case 5 of chronic mountain sickness: first determination twelve days after arrival from high altitudes; second determination sixty-four days after arrival; third determination one hundred and three days after arrival; fourth determination nine days after having spent a week at high altitudes; fifth determination made at high altitudes after eleven months of residence.

The disappearance of the polycythemia at sea level was accompanied in all cases by the cessation of the symptoms enumerated.

It is not known at the present time what is the factor or factors responsible for the abnor-

tion of the polycythemia which exists in some degree in all residents of high altitudes. Monge in his publications, already cited, has stressed the apparent similarity of the hematologic alterations found in these cases of chronic mountain sickness with those observed in polycythemia vera, and in his early papers,⁷ referring to the studies of Harrop and Heath⁸ in the latter disease, explained the accentuation of the high altitude polycythemia on the basis of a decreased alveolar permeability for the passage of oxygen. In another communication⁵ it was shown that the level of the absolute polycythemia found in residents of high altitudes has a striking direct correlation with the degree of the arterial oxygen unsaturation, suggesting that the latter factor constitutes the fundamental stimulus for the erythropoietic hyperactivity. In the presence of an abnormally high level of polycythemia, such as has

polycythemia vera there occurs very frequently an increase in the white blood cells with evidence of a pathologic leukoblastic activity as shown by the presence of immature cells in the peripheral blood. Such compromise of the leukocytic series is never found at high altitudes⁵ no matter how elevated is the level of polycythemia, and the same thing is true in the cases I am discussing. This fact, among others, is a most serious objection to the acceptance of the view that anoxia of one type or another is responsible for the development of polycythemia vera, which seems to be more adequately explained, as it has been suggested, by a disordered activity of the entire hemopoietic system.

The abnormal accentuation of the polycythemia may be related to an exaggerated response of the erythropoietic organs to the arterial oxygen unsaturation which exists at high altitudes and which depends on the low

The hemoglobin was calculated from the oxygen combining capacity determined in the Van Slyke manometric apparatus (Peters J. P. and Van Slyke D. D. Quantitative Clinical Chemistry, vol. 2, Methods, Baltimore: Williams & Wilkins Company, 1932) for the hematocrit a Wintrobe tube centrifuged for forty-five minutes at 3,000 revolutions per minute was used, the bilirubin was determined with a colorimetric procedure (Guzman Barrón S. Medicine 10: 77, 1931) and for viscosity a Hess viscosimeter was employed.

TABLE 2—Respiratory Investigations in Cases of Chronic Mountain Sickness

The gas analysis of the arterial blood obtained under anaerobic conditions from the radial artery was made in the Van Slyke manometric apparatus; the pulmonary capacity was determined according to Christie's method (Quart. J. Med. 11: 109, 1933) in the sitting position.

been found in our cases, three etiologic possibilities may be considered. It may be due, in the first place, to a heightened rate of erythropoietic activity independent of any known stimulus, a condition somewhat analogous to what occurs in polycythemia vera, or to a more active response on the part of the bone marrow to the anoxic stimulus which corresponds, in a normal degree, to the altitude at which the man lives, or, and this is the third possibility, the more accentuated polycythemia is the consequence of a more pronounced arterial unsaturation brought about by pulmonary, circulatory or other abnormalities.

With regard to the first possibility, I do not believe that there is any similarity between the normal or accentuated polycythemia of high altitudes and the one corresponding to polycythemia vera, beyond the increase in the red cell volume which is found in all these processes. All investigators agree on the fact that in

partial pressure of oxygen in the atmosphere. However, the fact that the arterial oxygen saturation in all but 1 of the cases is lower than what corresponds to the given altitude (fig. 4) suggests that the high level of polycythemia is a consequence of the increased anoxic stimulus, an assumption which has some support on the observations³ made in nearly 100 cases of silicosis developed in mines located in elevated places, in which the more pronounced arterial oxygen unsaturation, brought about by the pulmonary changes, was accompanied by a higher level of polycythemia. Incidentally it may be mentioned that the arterial oxygen saturation has been found to be unchanged in cases of polycythemia vera,⁹ a further point of differentiation between the two conditions.

There remains to be considered the possible mechanism responsible for the abnormal degree of anoxemia in these cases. We cannot rule out the possibility that this is a secondary effect, rather than a causal factor, to the increased pulmonary vascularity resulting from

the elevated circulating blood volume. Against this possibility is the observation⁹ that in polycythemia vera the arterial oxygen saturation is normal in spite of the tremendous increase in the cell volume, and the investigations of Dill, Christensen and Guzman Barron,¹⁰ who have pointed out that in residents of high

TABLE 3—Blood Volume Determinations in Cases of Chronic Mountain Sickness

Cases	Blood (Cc per kg.)	Plasma (Cc per kg.)	Red Blood Cells (Cc per kg.)	Hemoglobin (Gm per kg.)
1	101.3	31.1	168.1	55.1
2	157.1	37.1	111.1	81.1
3	113.6	19.0	109.2	33.3
4	211.1	27.7	173.1	53.1
5	167.2	41.1	193.1	34.4
6	180.0	40.8	188.8	36.6
7	180.2	37.8	117.3	48.6
8	197.8	40.2	156.7	46.5

The blood volume was determined by the method of Keith Rowntree and Geraghty (Arch Int Med 46:37 [Oct.] 1916) with the modifications of Hooper Smith Belt and Whipple (Am J Physiol 71: 93 1920). A 1.5 per cent solution of brilliant vital red was employed.

altitudes, even at the highest places with the corresponding polycythemia, the partial pressure of oxygen in the alveolar air plays the major role in the acquisition of this gas by the circulating hemoglobin. If the blood circulating normally in the lung capillaries acquires less oxygen than what corresponds to the tension of this gas in the alveolar spaces, the causative mechanism, ruling out changes in the hemoglobin affinity for oxygen, may be related to either one or both of the following alterations: (a) a deficient ventilation of the alveoli and (b) a decreased permeability of the alveolar membrane for the passage of oxygen. Condition a is brought about mainly by shallow breathing, a respiratory irregularity not found in the cases now under discussion and by a process of emphysema in which the loss of elasticity and the abnormal distention of the alveoli

Fig. 4—Arterial oxygen saturation in 8 cases of chronic mountain sickness: 2 cases studied at sea level; 4 cases observed at an altitude of 3,730 meters (12,240 feet) and 2 cases studied at an altitude of 4,540 meters (14,900 feet). Zone between heavy lines corresponds to the normal limits of variation of the arterial oxygen saturation at different altitudes.

make difficult the adequate removal and distribution of the air. Determination of the total lung volume and its subdivisions, made in 7 of the 8 cases studied (table 2), do not reveal the great increase in residual air which characterizes pulmonary emphysema; in addition, the vital capacity is only moderately reduced. It

seems, therefore, that an emphysematous condition of the lungs is not responsible in these cases for the abnormal degree of anoxemia.

As a final consideration, the possible existence of organic changes which would cause a decreased diffusion for oxygen may be briefly discussed. Roentgenograms (fig. 5) taken in 7 of the cases revealed a definite accentuation in the lung markings on both sides, persistent in 2 of them at sea level even after the disappearance of the polycythemia. In 5 cases the heart was abnormally large, as observed in the chest roentgenogram, and the electrocardiogram showed a right ventricular preponderance. In 2 the tracings were normal. In 2 cases there were clinical signs of cardiac insufficiency of the right type. The blood pressure was normal or moderately low.

These observations suggest the presence of fibro-sclerotic changes in the lungs of these men, changes which may correspond to those observed in the ill defined group in which the so-called Ayerza syndrome is placed and which frequently originates a pronounced unsaturation of the arterial blood. Several factors

Fig. 5—Appearance of the chest in case 6.

would favor at high altitudes the development of these organic changes in the lungs. Anoxemia, per se, may be an important factor. Campbell¹¹ has observed a thickening of the pulmonary arterioles in animals subjected for several weeks to a low barometric pressure and Buchner and Luft¹² have reported the occurrence of degenerative arterial lesions under similar experimental conditions. In 1930 I¹³ found pulmonary sclerosis in a man, not a miner living at an altitude of 4,500 meters (14,760 feet), but the value of this observation was limited by the absence of previous clinical data. The fibrous changes in the lungs developed after repeated pneumothorax may be due in great part to the lack of oxygen supply during the periods of collapse.

An increased tension in the pulmonary vascular bed has been found clinically¹⁴ and experimentally¹⁵ to cause arteriosclerosis. It seems that this portion of the vascular system is especially susceptible to variations in pressure. No direct measurement of the pulmonary arterial pressure has been made at high altitudes but its possible elevation may be inferred from the permanent congestive condition and the greater volume of blood contained in the lungs⁶ and from the high frequency of right ventricular preponderance in the electrocardiograms taken in apparently healthy natives.¹⁶ The frequent respiratory infections and the

high viscosity of the blood may constitute additional factors in the tendency to develop anatomic alterations in the lungs at high altitudes.

The disappearance of the anoxemia and of the resulting polycythemia on descent to sea level is not a basic argument against the possibility that organic changes of the nature described are responsible for the increased arterial unsaturation found at high altitudes in some cases of chronic mountain sickness. It must be considered that the passage of oxygen through the alveolar membrane corresponds to a physical process of diffusion and that a thick membrane may constitute an obstacle for an oxygen with a partial pressure of about 50 mm. of mercury (41.5, 53.4 and 47.2 in cases 1, 2 and 4, respectively, studied at high altitudes) in the alveolar spaces, but it may allow a normal passage when such tension is raised at sea level on account of the higher barometric pressure.

The study of a greater number of cases and the anatomic investigation of the lungs and other organs after death will be necessary for the final understanding of the etiologic mechanism responsible for the hematologic alterations found in some cases of chronic mountain sickness. In this field, as in many others, the morphologic aspects have been unduly neglected in favor of the functional and chemical approximation.

OCHRONOSIS OF THE SCLERA AND CORNEA COMPLICATING ALKAPTONURIA

REVIEW OF THE LITERATURE AND REPORT OF FOUR CASES

JAMES W. SMITH, M.D.
NEW YORK

Medical works of the sixteenth and seventeenth centuries cite instances of urines which were black when voided or which darkened on exposure to air. In 1858 Boedeker¹ found in the urine of a patient with glycosuria a second reducing substance, not a sugar, to which, on account of its behavior toward alkalis, he assigned the name alkapton. Marshall² in 1887 discovered the true nature of alkapton to be glycosuric acid. Wolkow and Bauman named the reducing substance homogentisic acid because it is a homologue of gentisic acid and showed that the peculiar properties of so-called alkaptonuric urine is due to this acid. Garrod³ considers alkaptonuria as an inborn error of metabolism which is present at birth. When first voided, the urine of an alkaptonuric person appears of normal color but after contact with air undergoes a change through various shades of brown to actual blackness. The addition of an alkali will accelerate the color change. Linens and woollens moistened with the urine are stained as if by a photographic developer.

Alkaptonuric patients cannot effect the complete catabolism of the tyrosine and phenylalanine contained in the proteins of the food and tissues, so that an

intermediate product, homogentisic acid (hydroquinone-acetic acid), remains. Homogentisic acid shares with other similar aromatic compounds the property of blackening on oxidation, which explains the characteristic property of alkapton urine. At least 200 cases of alkaptonuria have been reported. The disorder shows a family tendency, particularly in children of consanguineous parents, and is inherited as a recessive mendelian characteristic.

Virchow⁴ in 1866 observed discoloration of cartilage during a postmortem examination. Under the microscope the pigment granules appeared pale yellow or ochre. He named the disease ochronosis. This observation passed unnoticed until a second case was reported twenty-five years later. In 1902 Albrecht⁵ first suggested that alkaptonuria was the cause of ochronosis. Osler⁶ in 1904 described the clinical features of the disease—pigmentation of the sclera, ear cartilage and a peculiar stilted gait. In 1906 Pick⁷ reported a case due to prolonged use of phenol dressings to leg ulcers, which he described as exogenous ochronosis in contrast to the endogenous form of congenital origin associated with alkaptonuria.

The most plausible explanation of the mode of production of the pigment in the disease is by Pick. He suggested that through the action of the oxidative ferment tyrosinase, the phenol substances in the exogenous group and the homogentisic acid molecule in the endogenous group are changed into melanin pigment, which is deposited in the tissues. Abderhalden and Guggenheim⁸ believe that an accumulation in the human organism of excessive and abnormal amounts of substances possessing the oxyphenyl group leads to the production of melanin pigments by ferment action. Both the exogenous and the endogenous group contain this chemical entity. Clemens,⁹ Wagner¹⁰ and Landois¹¹ demonstrated the presence of pigmentation in cartilages and other structures.

Allard and Gross¹² described the deforming arthritis of the larger joints in alkaptonuria. In the family, reported by Umber and Burger,¹³ of 8 children of an alkaptonuric father and a normal mother 4 were alkaptonuric. The alkaptonuric children suffered severely from articular lesions. The 4 nonalkaptonuric children were entirely free from arthritis. Soderbergh¹⁴ in 1915 emphasized the roentgen changes in the vertebral column and suggested the name *ostitis deformans alkaptonurica*.

Clinically, ochronosis is first recognized by a blue coloration of the ears, first of the concha and antihelix and later of the tragus and antitragus. The darkened cartilages of the ears feel abnormally firm. In many instances the first sign is gray coloration of the sclerae.

or brown pigment spots near the insertion of the rectus tendons. Areas where the blackened cartilages or tendons show through the overlying skin appear blue. Later, the nasal cartilages become stained, the nose may appear blue and a butterfly-shaped brown pigmentation of the skin of the face develops. Less frequently, the knuckles of the hands are blue owing to staining of the tendons, and in rare instances the thenar and hypothenar eminences are pigmented brown.

The postmortem examination reveals deep brown or even black pigmentation of the cartilages, fibrocartilages, fibrous tissue and epidermis, as well as areas of degeneration, notably atherosclerotic plaques, albuminous masses and concretions.

GENERAL REVIEW OF THE LITERATURE

The importance of the scleral pigment spots has been stressed by internists since 1895, but ocular ochronosis has never been described in an American textbook on ophthalmology. I have reviewed every paper on ochronosis with particular reference to involvement of the eye.

Scant credit is given to American authors for their contribution to the clinical knowledge of alkaptonuria and ochronosis. Marshall in 1887 reported the first case of alkaptonuria in this country and discovered homogentisic acid. A case of alkaptonuria described by Ogden¹⁵ in the *Zeitschrift für physiologische Chemie* in 1895 is revealed as having been presented before the Milwaukee Medical Society in 1890. Hecker and Wolf are universally credited as the first to describe the discoloration of the eyeball in 1899. Scleral pigmentation was first observed by Osler four years earlier. A historical note of ophthalmologic importance is that Osler's diagnosis of ochronosis in his first and second American patients was based on the eye changes which he described in minute detail. The second patient, whose condition was reported originally as alkaptonuria by Marshall, was a brother of the patient seen by Osler in 1895.

The third case of ochronosis was established by letter when Ogden wrote "the color of the inside of each concha is a pearly light grayish lead blue, like the inside of our common mussel shells."

Harvey Cushing's¹⁶ finding that the first British case of ochronosis had been diagnosed as Addison's disease does not appear in the medical literature and is worth recording.

The most authoritative monograph on ochronosis is the one hundred and eighty-nine page doctorate thesis by Valdemar Poulsen¹⁸ of Copenhagen in 1909. Every author outside of his country has quoted this reference as of German origin. No one ever sought to explain how a 30 year old investigator had the good fortune to observe 9 cases of such a rare disease. Through the courtesy of the New York Academy of Medicine, a copy of the thesis was obtained from the library of the Surgeon General's Office. Poulsen records the optic disorders present in 7 cases and 2 in which postmortem pathologic sections were made. Fifteen colored drawings depict in a graphic manner the outstanding clinical and pathologic manifestations in ochronosis.

Ochronosis from the standpoint of the internist is best presented by Howard and Mills²² in 1941 and is based on a world summary, unfortunately incomplete, of 55 cases.

Pomerantz²³ has found the most characteristic roentgen findings of alkaptonuric ochronosis in the spine, pelvis, shoulder and knee joints and costal cartilages. Fixation of the spine is effected by ankylosis of the vertebral bodies and their joints. The intervertebral disks are calcified and appear as elliptic opaque wafers, particularly in the lumbar areas. He believes that the density of the intervertebral disk is due to secondary calcification following degeneration of the cartilage induced by deposition of homogentisic acid.

THE EYE CHANGES IN OCHRONOSIS

A complete review of this subject does not appear in the medical or ophthalmologic literature. In the accompanying tables positive eye changes in 60 cases are shown: in 3 the changes are of undetermined origin, in 2 due to melanuria, in 20 to carbolochochromosis and in 35 they are changes complicating alkaptonuria. In 18 cases the eye changes are tabulated as negative although in 14 they were not recorded or observed.

Edmund Jensen in 1904 noted the scleral pigmentation in a case but the diagnosis was not established.

Scope of Tables

	Condition	Number of Cases
Table 1	Alkaptonuria	35
Table 2	Carbolochochromosis	20
Table 3	Melanuria	2
Table 4	Undetermined etiology	3
Table 5	Without eye changes (negative or overlooked)	unrecorded
		18
		78

until Poulsen (case 3) began his research three years later. Schultz-Zehden²⁴ published a short report on 2 cases in 1908. The third ophthalmologist to examine an ochronotic eye was Fleischer (Kolaczek's case 1).

The only comprehensive paper on the subject, including the first slit lamp microscopic examination, was published by Sallmann²⁵ in 1926. He confirmed the presence of pigment granules in the corneal periphery first observed grossly by Hecker and Wolf²⁶ in 1899. I shall describe this definite finding in cases 3 and 4.

Schreiber²⁷ described the possibility of involvement of the skin of the lid and stated that arsenic melanosis, toxic diffuse goiter and Addison's disease must be considered in differential diagnosis.

A case of conjunctival pigmentation was studied biomicroscopically by the French ophthalmologist de Cluj²⁸ and the gross scleral pigmentation by Anderson,²⁹ an Englishman, in 1937. Duke-Elder's³⁰ textbook is the first in the English language to mention

ochronotic pigmentation of the sclera and conjunctiva. Although Sallmann's paper is cited, no reference is made to corneal disorder.

It is now possible to evaluate the changes that may take place. The skin of the lower lids was pigmented black in 1 case (Ashburn³¹), tarsal conjunctivas and scleras were discolored in 2 (Graeffner³² and Fleischer), pigment granules were present in the corneas and scleras in 2 (Hecker and Wolf and Sallmann), scleras and bulbar conjunctivas were pigmented in 3 (Fleischer, Poulsen and Beddard³³), and the conjunctiva only was pigmented in 3 (Osler and Ogden,¹⁶ de Cluj and Diebold³⁴). In Sallmann's case the scleras, conjunctivas and corneas were pigmented. The scleral spots were present in 57 of the 60 cases tabulated, varying in size from that of a pinhead, a lentil seed or a bean, in shape either triangular, circular, vertical striped or like parentheses including the corneas, and in color from brown to blue or brown-black.

I have collected 23 cases (21 with eye changes) that have been omitted from previous world summaries. In every case of proved etiology reported since 1910 (except Fishberg's), eye changes were found. Formerly it was thought that ochronosis did not develop in alkaptonuria until middle age or later. Positive eye findings in Poulsen's patient at the age of 23 (and in his sixth patient at 24), de Cluj's at 25, Ashburn's at 27½, Baldwin's³⁵ at 31 and Kolaczek's at 30 and 35 indicate that ochronosis can be detected at an earlier age. Of ophthalmologic significance is the definite statement by Poulsen that the eyes were pigmented before the ears in his cases 3, 5, 8 and 9.

The parents of my second patient were first cousins, 3 brothers are alkaptonuric, 1 or 2 of whom have blue ears, 3 of 4 daughters are alkaptonuric and 2 showed premature calcification of the costal cartilages suggesting early ochronosis, and a grandson has alkaptonuria. This is probably the first family pedigree in which the disease is expressed as a dominant instead of a rare recessive mendelian characteristic. No treatment is known which affects the course of alkaptonuria and ochronosis except the prohibition of consanguineous marriages in affected families.

No investigator has had an opportunity to section an ochronotic globe. Pope's specimen examined grossly post mortem revealed a deposit of pigment in the superficial layers of the sclera. The microscopic finding of "ordinary fine granular pigment in the sclera," erroneously quoted in several papers, referred to the pathologist's report on the ear and rib cartilages.

Some authors have stressed the presence of dilated conjunctival vessels over the scleral spots as a factor in the production of pigment. Actually the avascularity and sluggish metabolism of the sclera accounts for the formation and storing of homogentisic acid, as occurs elsewhere in the body. Fishberg and Dolin⁴¹ believe that the system homogentisic acid-benzoquinone acetic acid fulfils all the criteria of a reversible oxidation system. "Some light is thrown on the old question as to why the pigment in ochronosis is so strictly

localized in the cartilages and scleras. Virchow states in the original description, 'I will name this condition ochronosis. It is strictly localized in those parts that are without nerves and blood vessels.' These are the regions where there can be no poisoning effect of hemoglobin. Hence the quinone from the homogentisic acid can be formed and at the pH of the body fluids instantly form the colored product characteristic of ochronosis."

The localization of the scleral spots to the palpebral fissures must be related to the catalytic action of light in stimulating pigment formation in exposed areas of the body.

An authoritative work on metabolic diseases⁴² in the section devoted to ochronosis does not mention eye pigmentation either as a symptom or as an aid in diagnosis. On the other hand "black sclera" is the heading found in a textbook on symptom diagnosis.⁴³ While this concept is extreme (only the cartilages become black), credit should be given to an American internist for attempting to classify an ophthalmologic entity.

REPORT OF CASES

CASE 1—History.—B. N., a white man aged 44, a cameraman seen Feb. 12, 1942 through the courtesy of Dr. Emanuel Stern had no complaints about the eyes but three months previously had experienced a sensation of pain in the lower part of the lumbar region. He had corrected vision with myopic astigmatic lenses of 20/20, in both eyes. His mother and father were first cousins and the patient was born in Turkey. He stated that there was no history of alkaptonuria and that his 2 daughters and 1 son were in perfect health.

Examination.—Ophthalmologic examination showed in the palpebral fissures a conjunctival band of brownish color extending for 10 mm temporally in the right eye and 1 mm temporally in the left eye. By slit lamp microscopy a group of very faint pigment dots were seen near the temporal limbus at 8-30 o'clock with high power magnification. Nasally in the left eye very faint pigment dust was present in the horizontal meridian and conjunctival portion of the limbus without definite color. The changes were not sufficiently advanced to be considered pathologic.

In each ear were seen two discrete areas of blue about the hue of a dilated vein placed symmetrically near the concha and antihelix. The patient was not conscious of this abnormal coloration until it was demonstrated to him.

A laboratory examination was made at the chemical laboratory of the Hospital for Joint Diseases by Dr. Aaron Bodansky. Homogentisic acid was recovered from a specimen of urine submitted March 14. Tests for alkaptonuria gave positive results.

A report of the roentgen examination made by Dr. Maurice M. Pomerantz is as follows: "In the dorsal region, there is a moderate kyphosis. There is a distinct narrowing of all intervertebral joints with some eburnation of the articular surfaces of all vertebrae. In the lower dorsal area there is extensive calcification of the intervertebral cartilages associated with moderate hypertrophic marginal changes."

"In the lumbar area there is no unusual accentuation of the lumbar lordosis. The lumbosacral angle is definitely reduced. There is likewise distinct narrowing of all lumbar vertebrae associated with the formation of fairly large osteophytes on the anterior surface of all the segments. The articular surfaces of the vertebrae are moderately eburnated and there is some suggestion of beginning calcification of the intervertebral disks between the first and second and the fourth and fifth lumbar vertebrae."

"Examination of both shoulder girdles does not disclose any essential change in the width of either articulation. The heads of the humeri and glenoid fossae are intact. There are no calcific deposits in or about either joint."

Conclusion The changes in the spine are those usually associated with alkaptonuria and ochronosis.⁴³

CASE 2—History—M. N., a white man aged 53, a film inspector, examined on April 22, 1941 through the courtesy of Dr. Pomernitz, is the older brother of B. N. He was also born in Turkey. Six brothers and 3 sisters are living, a seventh brother died thirty years ago following an attack of typhoid. The patient's wife states that 3 of his brothers are alkaptonuric and 1 or 2 brothers have blue ears. The patient has 4 daughters, and the 3 younger ones are alkaptonuric. A grandson aged 4 voids urine which stains diapers black.

The patient complained of pain in the shoulder joints and gave a history of vague gastric distress.

Examination—The ears have been discolored for twenty years. The patient stands with a slight stoop and the knees flexed. There is a decided dorsal kyphosis, and lumbar lordosis is increased. There is a peculiar gray-blue discoloration of the head and neck and in numerous scattered areas over the body. The pigmentation appears to be most pronounced in the ears and about the nose.

All tests for alkaptonuria gave positive results, but the Wassermann reaction was negative.

Roentgenograms show narrowing of the shoulder joints with considerable eburnation of the head of the humerus and glenoid. There is narrowing of the intervertebral joints with calcification of the cartilage and extensive calcification of the costal cartilages. The lateral view shows calcification of the intervertebral cartilages and spinal ligaments posteriorly. Roentgenograms of 2 daughters reveal intense premature calcification of the costal cartilages.

Vision in both eyes is 20/20 with hyperopic correcting lenses. A faint yellow-brown conjunctival discoloration is present in the palpebral fissures extending 5 mm temporally from the limbus and nasally in each eye 3 mm from the limbus. The nasal discolorations are of a lighter hue and the left is more diffuse and browner than the right.

Slit lamp examination showed that the corneas are normal. One discrete, dark brown pigmented dot was seen in the left limbus conjunctiva. Examination otherwise was negative; no pigmentation was present in the conjunctiva or sclera and the faint staining seen grossly appeared related to increased color intensity in the pinguiculae.

The ears are a slate gray-blue and are unduly rigid. The cartilages appeared opaque by transillumination.

CASE 3—History—H. G., aged 65, a former bank messenger, was admitted to the Third (New York University) Medical Division, Welfare Hospital, service of Dr. J. Murray Steele on July 14, 1939.

The patient had sustained a skull fracture in 1929 and a fracture of the lower third of the right femur in 1939. Between 1929 and 1939 he had been hospitalized four times at various institutions, and the diagnosis of ochronosis had not been made. The diagnosis on admission was malunion of a fractured right femur. In 1932 an iridectomy and a cataract extraction were

performed on the right eye and the same operations were performed on the left eye one year later. At this time the ophthalmologist called the patient's attention to a colored spot in the left eye.

The family history was negative.

Examination—The urine turned dark brown to black on standing, a change which developed almost instantly following

Fig. 3 (case 3)—Temporal ochronotic spot of average size (3 mm by 5 mm) in alkaptonuria of long standing (depression of frontal bone after skull fracture).

the addition of ammonia water. Benedict's solution reduced dark green with yellow precipitate formation, alkapton bodies were present.

On physical examination there was a faint cyanotic tint in both ears and transillumination revealed diffuse pigmentation of the aural cartilages as noted in case 2.

Fig. 4 (case 3)—Same characteristics of intervertebral cartilages shown in figure 2.

Ascorbic acid was given to the patient in an attempt to influence the excretion of homogentisic acid, without effect. These experiments have been reported by Sealock, Galdston and Steele.⁴⁴ Other vitamins were given to the patient without affecting the output of homogentisic acid.

^{43a} Fishberg, Ella H. The Instantaneous Diagnosis of Alkaptonuria on a Single Drop of Urine. *J. A. M. A.* 119: 882 (July 11) 1942.

⁴⁴ Sealock, R. R., Galdston, M., and Steele, J. M. Administration of Ascorbic Acid to an Alkaptonuric Patient. *Proc. Soc. Exper. Biol. & Med.* 44: 580 1940.

Roentgen examination was done by Dr Henry K. Taylor and showed hypertrophic arthritis of the shoulders and spine, intervertebral disks almost completely obliterated and considerable decalcification of the spine, the right hip showed almost complete absorption of the head of the femur, the neck formed an articulation with the acetabular shelf prostatic cal-

Fig. 5 (case 4)—Pigmentation of scleras in alkaptonuric ochronosis. The left lesion nasally is unusual in length and is partly covered by the eyelid.

culi were present. There was considerable calcification of the vessels of the legs and a calcareous plaque in the aortic arch.

With the aphakic lens corrected vision of the right eye is 20/20 minus and of the left eye 20/40. A faint secondary cataractous membrane accounts for subnormal vision in the left eye. The fundi are grossly normal. Transillumination of the sclera suggests some thinning at the sites of insertion of the external rectus tendons.

Slit Lamp Biomicroscopy.—Right Cornea. One and five-tenths mm from the temporal limbus three brown pigment spots are situated very superficially, probably just beneath Bowman's membrane; a single larger pigment dot is seen beneath the conjunctival layer of the cornea. No pigmentation is present nasally. A defect in Descemet's membrane is noted at 5 o'clock. The posterior third of the cornea is pigmented, probably of traumatic origin after the cataract extraction.

Right Sclera. Three mm temporal from the limbus a slate gray purplish area 2.5 mm wide and 6 mm high is seen between 8 and 10 o'clock levels of the cornea, situated superficially in the sclera. By slit lamp examination brown pigmentation appears under the conjunctival vessels. The pigment is filamentous or spiral and some areas simulate incompletely closed rings. The pigment is not arranged in clumps or groups as portrayed in the drawing of de Cluy reproduced in Duke-Elder's textbook.

Three mm nasal from the limbus a faint gray area 2 mm wide and 5 mm high is seen between the 3 and the 5 o'clock level of the cornea, situated more superficially in the sclera and pigmented a brownish yellow in the slit lamp beam.

A 5 mm zone of sclera beyond the limbus appears light blue. The remainder of the sclera externally is normal, although transillumination suggests uniform thinning.

Left Cornea. Temporally eight fine round, brownish yellow spots are seen posterior to the fine limbus conjunctival vessels in the substance of the cornea. Nasally, 2 mm from the limbus in the 9 o'clock meridian two tiny pigmented spots appear just behind Bowman's membrane.

Left Sclera. Three mm temporal from the limbus a slate gray purple area 3 by 5 mm surrounded by a pink border of blood vessels is seen between the 2 and the 4 o'clock level of the cornea. A similar distance from the cornea nasally a small faint blue area 1 by 2.5 mm appears between the 9 and the 9:30 level of the cornea. Slit lamp microscopy reveals the same brown spiral and ringlike pigmentation as was noted in the right sclera. The conjunctiva moves over the scleral areas during the winking reflex and does not appear to be involved.

CASE 4—History.—F. D., a cigar maker aged 61 when admitted to the Welfare Hospital on June 10, 1940, service of Dr J. Murray Steele, had previously been studied in the service of Dr I. O. Woodruff at Bellevue Hospital and the roentgen findings were reported by Pomrantz, Friedman and Tunick.⁴⁵

The patient's father died of unknown causes many years ago and his mother died of pneumonia at the age of 58. Two brothers and 1 sister are alive and well. There is no history of consanguinity and no other member of the family has suffered from alkaptonuria.

He had amaurosis of the left eye following recurring attacks of iritis after an injury in 1918. During the past eighteen years he has suffered from severe pain in the lower part of the back. Later he experienced pain and stiffness in the shoulders and right knee which are now so intense as to be almost completely disabling. The patient walked with a great deal of difficulty, had limited range of motion at the knees and could not abduct his arms. He stated that for thirty five years he had noted a bluish discoloration of the ears but that he had never observed anything peculiar in the color of the urine. For the past thirty six years he has observed yellow discoloration of the right palpebral fissure temporally and in the left fissure nasally. Prominent dark spots in the sclera were observed by his friends about six years before admission.

Examination.—The patient's spine appears fixed. His head is thrust forward and the arms hang limply at his sides. The knees are flexed. The skin particularly on the head, neck and chest shows peculiar mottled bluish and in some areas brownish pigmentation or discoloration. This pigmentation is most noticeable in the ears and at the tip of the nose. In the region of the small joints, particularly of the hands, are peculiar bluish linear discolorations which seem to be beneath the skin.

Roentgen examination showed narrowing of the vertebral articulations with extensive calcification of intervertebral cartilages, peculiar granular osteoporosis and ankylosis of the spine with loss of normal curves, calcification of the interpubic cartilage with similar depositions in the soft tissues of the hip joints, partial synostosis of the right sacroiliac joint and fusion of the lumbar spinous processes, calcareous deposits in the patella tendon and popliteal space, and unusually advanced Monckeberg's arteriosclerosis. Roentgenograms of the ears revealed the presence of opaque deposits simulating otitis media.

Ophthalmologic Findings. Vision of the right eye is 20/15 and the left eye is blind following recurring, specific iridocyclitis.

Fig. 6 (case 4)—Showing the right nasal and left temporal scleral spots. The mottled pigmentation of the skin of the nose is apparent.

starting in 1917. Ophthalmoscopic examination shows the media to be clear, with physiologic excavation of the optic nerve, prominent and retinal arteriosclerosis. In the blind eye there are numerous posterior synechiae following recurring attacks of iritis, probably of specific origin. Glaucomatous excavation of the optic nerve and retinal arteriosclerosis are seen. The clinical diagnosis was amaurosis following secondary glaucoma.

⁴⁵ Pomrantz, M. M., Friedman, L. J. and Tunick, I. S. Roentgen Findings in Alkaptonuric Ochronosis. *Radiology* 37: 295 (Sept.) 1941.

Slit Lamp Biomicroscopy—Right Cornea In a zone 0.5 to 2 mm inside of the temporal limbus are seen groups of oval pigment spots situated in the superficial layers. The spots are darker brown and larger than the ones in the cornea in case 3. Four spots of pinhead size are present at 9 o'clock, toward 7 o'clock there are five more, and inferiorly are scattered many smaller and finer ones. The periphery of the cornea at 9 o'clock is opaque. At the limbus is a groove 2 mm vertical and 1 mm horizontal resembling marginal atrophy. The thickness of the cornea is decreased about one half at this point. In a zone 2.5 mm inside the nasal limbus between 2 o'clock and 4 o'clock are nine large and many powder grain dark brown spots.

Right Sclera Five mm temporal from the cornea a slate purplish area 2 mm wide and 5 mm high is seen surrounded on each side by injected conjunctival vessels. The upper edge lies opposite the 9 o'clock corneal level while the inferior edge extends lower than 7 o'clock level and is covered by the lower lid. Pigmentation of the conjunctiva is not seen microscopically. The slate gray change is definitely in the sclera. The subconjunctival vessels are not increased in number over that seen normally in the palpebral fissure or about a pinguicula of an aged patient. A thinning of the sclera is suggested in this area.

Four mm nasal from the limbus is seen a triangular purplish slate gray area measuring 9 mm high, 6 mm at the widest point, tapering to 2 mm superiorly and 1 mm inferiorly and lying between the 1 and 4 o'clock levels of the cornea. The conjunctival vessels are injected along the nasal border. Pigmentation of the conjunctiva is not seen microscopically. The slate gray area lies beneath the conjunctiva which moves freely above it. Episcleral blood vessels are increased over those seen in a normal eye.

Left Cornea The pigment spots are so numerous that they can be seen without magnification. Near the temporal limbus about thirty dark brown spots are noted, some pinhead size and others as small as powder grains. They are located in the most superficial layers of the cornea, probably just below Bowman's membrane. Several appear like droplets, and a convex reflection is seen suggesting that some of the pigment spots have a different refractive index.

Near the nasal limbus about thirty-five spots are seen, also of varying sizes. Some lie deep but most of the pigmented areas are in the superficial layers of the cornea.

Left Sclera Five mm temporal from the limbus is seen a slate gray area measuring 2 by 5 mm surrounded by faint conjunctival injection lying between the 3 and the 6 o'clock level of the cornea. The conjunctiva is not pigmented and the number of conjunctival and episcleral vessels are increased over normal.

The most prominent ochronotic patch is seen 3 mm nasal from the limbus of slate gray and is devoid of the purple hue noted in the right sclera nasally. It measures 5 mm wide in the middle third, 3 mm in the upper and lower thirds and 10 mm high. The upper edge corresponding to the 11 o'clock corneal level is covered by the upper lid, and the inferior edge extending lower than the 6 o'clock meridian is well covered by the lower lid. The temporal and nasal edges are surrounded by injected conjunctival vessels. The pinguicula lies in front of the colored scleral zone. Microscopically the conjunctiva is unpigmented. The sclera is diffusely colored a slate gray. Grouped pigmentation is not seen. The scleral sites nasally and temporally seem indented, suggesting thinning of these areas.

The distribution of pigment in the four scleral areas followed a similar pattern. In the center it appeared darker and mounted. At the periphery the slate areas changed in color from brown to yellow and imperceptibly into adjoining normal sclera.

DIFFERENTIAL DIAGNOSIS

In melanosis bulbi small flecks or large islands of dense slate blue or brown pigmentation appear in the sclera. The sites involved are not limited to the palpebral fissure. Basil Graves⁴⁶ and Culler⁴⁷ described

scleral plaques near the nasal limbi in patients over 60 years of age which vary in size from pinpoint to approximately 2 mm in the horizontal plane and 6 mm in the vertical plane. They are slate gray because the ciliary body shows through the area of increased transparency. Pillat⁴⁸ has reported a senile degeneration of the sclera over the tendinous insertions of the rectus muscles which appears as a dark band of dirty gray. He does not believe that the finding is related to pigmentation of the bulbar conjunctiva, as seen in arsenic melanosis, ochronosis or Addison's disease. Scleral ochronosis is readily differentiated by its superficial localization in the palpebral fissures temporally and nasally. The progressive color changes from faint brown to slate blue or black when associated with blue ears, alkaptonuria and definite roentgenographic changes establishes the diagnosis beyond question.

Fig 7 (case 4).—In addition to the points mentioned in legend for figures 2 and 4 there is likewise well defined osteoporosis and slight hypertrophic changes are present at the margins of all the vertebrae.

The occasional involvement of the skin of the lid may suggest the bronzelike pigmentation of Addison's disease or the dark discoloration associated with generalized argyrosis.

In the conjunctiva by slit lamp microscopy the brown pigment, when present, appears subepithelial, like cystic dilatations near the borders of the scleral spots, and is deposited in crescent, spiral or open ring formations. Congenital pigment flecks which sometimes increase in size and the fine granular epithelial and subepithelial pigment seen in Addison's disease do not present the same microscopic picture.

The corneal involvement is characteristic. The presence in the superficial layers near the temporal and nasal limbi of discrete brown pigment spots which by retroillumination appear like oil droplets on water cannot be confused with any other slit lamp biomicroscopic finding.

SUMMARY

The total number of cases of ochronosis in the literature has been increased to 82 by the addition of 23 omitted from previous reviews and the 4 cases reported here from the ophthalmologic angle

Alkaptonuria is a relatively common disease. Endogenous alkaptonuric patients may exhibit signs of ochronosis before the age of 30.

The diagnostic triad in ochronosis is pigmentation of the ears and scleras, urine that darkens on exposure to air and osteoarthritis.

CONCLUSION

Ocular ochronosis was found as a complication in every proved case but 1 since 1910.

Pigment spots in the corneas superficially near the temporal and nasal limbi represent a slit lamp biomicroscopic finding which is diagnostic of advanced ochronosis.

Scleral ochronosis develops gradually and simultaneously with pigmentation of the ear cartilages or may be one of the first signs of ochronosis.

Careful ophthalmologic study should reveal abnormal pigmentation of the scleras or conjunctivas in patients seen early and pigment spots in the corneas in alkaptonuric patients past middle age.

1016 Fifth Avenue

ABSTRACT OF DISCUSSION

DR M L BERLINER, Brooklyn. In a case which I examined the conjunctival pigmentation was seen in the form of oval brownish spots which under high power were composed of granules in a partially closed ring arrangement. The appearance and disposition of the pigment in the cornea are typical. It is found in Bowman's zone as small brownish discrete globules resembling oil droplets symmetrically arranged. It would be interesting to speculate on whether the pigment migrates along the basal cell layers of the conjunctival epithelium into the cornea or whether it arises in situ. The fact that the pigment tends to develop in the nearly avascular tissues such as tendons and cartilages might cause one to favor the latter idea. Although alkaptonuria is a symptom of ochronosis it may occur as an isolated finding. Two types of ochronosis are known: (1) the endogenous form, an inherited metabolic anomaly associated with alkaptonuria, and (2) the exogenous form, resulting from phenol (carbolic ochronosis) or benzene poisoning, including such substances as dinitrophenol, paradichlorobenzene, aniline, epinephrine and similar aromatic compounds. All these when ingested tend to form phenol derivatives in their intermediate metabolism. These intermediate products at the slightly alkaline pH of the body fluids polymerize into pigments. An analogous reaction occurs with epinephrine solution, which when left exposed to air turns dark. In the first or endogenous group (represented by Dr Smith's cases), there is a total inability to destroy tyrosine and phenylalanine contained in the proteins of food and tissues, resulting in the excretion of homogentisic acid, an intermediary product. This substance is excreted into the urine. After many years as the result of the action of tyrosinase there is a deposition of a black pigment similar to melanin in the cartilages and tendons. I reported 2 cases of cataract from poisoning by inhalation of paradichlorobenzene vapor (a commonly used moth repellent). In 1 of these cases phenol derivatives were found in the urine. The urine turned dark on standing. Several months after the patients were removed from the action of the fumes they suddenly acquired cataracts. The posterior cortex of the lens of a woman aged 30 became definitely dark brown of the so called nigra type. This was followed by a rapid swelling of the cortex. I would suggest that biochemical studies of tissues and excretions be made in such cases as black cataracts, melanosis oculi, whorl-like keratitis, Hudson's line and others which are characterized by melanin or melanin-like pigmentation.

DR JAMES W SMITH, New York. A pocket flashlight held behind the ear will delineate the opaque cartilage, affording a simple clinical diagnostic test. The ochronotic areas cannot be transilluminated. The cases of ochronosis known definitely to be of alkaptonuric origin total 45. Of these 31 (69 per cent) occurred in males and 14 (31 per cent) in females. This finding contrasts with statements in the literature that the sex incidence is about equal in men and in women. Many cases of alkaptonuria and ocular ochronosis were never recorded. In the family of my second patient alone there are 5 with alkaptonuria and potential ochronosis not yet investigated. It is important to remember that the eye picture is variable and progressive, starting as a faint, diffuse, brown discoloration in the palpebral fissure and ending as a slate colored and conspicuous brown black scleral spot. I arranged my 4 cases chronologically in order to demonstrate this point. The ophthalmologist should be able to aid the internist in detecting ochronosis by slit lamp examination of young adults. There is a possibility that some day homogentisic acid may be recovered from tears just as it can now be detected in urine. Every case of alkaptonuria at birth is a potential case of ochronosis. By roentgenographic examination cases can be diagnosed in the second decade or possibly even sooner. Scalock, Gladston and Steele have suggested that the continued high intake of vitamin C in early life may prevent the deposition of melanotic pigment in later years.

IRREGULAR ISOAGGLUTININS

ISRAEL DAVIDSOHN, MD
CHICAGO

The concept of what constitutes irregular isoagglutinins has undergone profound changes during the last forty years. Isoagglutination means clumping of red cells by serum or plasma of an individual of the same species; isoagglutinins are the clumping antibodies in the serum. Heteroagglutination or clumping of red cells by serum of an individual of another species has been known at least since 1874, when Landois published a monograph on blood transfusion.¹ It seemed natural that bloods of different species should manifest incompatibility, but the observation by Landsteiner² in 1900 of clumping in a mixture of bloods of two healthy human beings was a surprise, especially since it was noted in some combinations of bloods and not in others. Actually a number of publications which followed Landsteiner's original report referred to isoagglutination as a manifestation of disease. Some writers were quite certain that it never occurs in health,³ others conceded that it may occur in an occasional normal individual, though as a rule it is abnormal.⁴ Later investigations confirmed Landsteiner's original concept of isoagglutination as a normal physiologic phenomenon.

According to Landsteiner, every person has in his serum agglutinins for the agglutinogens which he lacks in his blood. The formulas of the four blood groups

irc O (anti A anti B), A (anti B), B (anti A) and AB (o)

What then are irregular isoagglutinins? One could define them as isoagglutinins which are not found regularly in the normal pattern of blood groups and types. The term type is used for blood factors other than A and B, for instance for the properties M and N.

Several deviations from the previously mentioned formulas are known, some of practical importance. One of them is based on the discovery made by von Dungern and Hirschfeld in 1911 that the agglutinin Λ occurs in two forms, a strongly agglutinable Λ_1 and a weakly agglutinable Λ_2 . About four fifths of group A and AB bloods have the stronger Λ_1 factor, the rest have the weaker Λ_2 factor. As a result, four subgroups have been recognized A_1 , A_2 , A_1B and Λ_2B . Recently a still weaker form of group A has been demonstrated subgroup Λ_3 . A voluminous literature has accumulated on the question of whether these subgroups represent merely quantitative or qualitative differences. The proponents of a qualitative nature of the differences seem to have the better of the argument. In connection with the subject under discussion it is of interest that there are occasionally so-called irregular isoagglutinins in these subgroups reacting with the A factor of the other variety. The rare agglutinin in the serum of the subgroup A_2 or A_2B clumps red cells of subgroup A_1 or A_1B and is known as the α_2 agglutinin. The still more infrequent agglutinin in subgroup A_1 or Λ_1B agglutinates red cells of subgroup Λ_2 and Λ_2B and is called α_1 . The latter agglutinin has the further unusual property that it clumps the normally magglutinable group O. According to some, the α_1 agglutinin is reacting specifically with the factor O and with A_2 only because A_2 is as a rule heterozygous and as such contains the recessive O factor. The practical significance of these two irregular agglutinins is that they may lead to confusion in blood grouping and cross matching tests. It was shown that α_1 and α_2 react best at temperatures between 15 and 18 C and therefore belong to the group of so-called cold agglutinins to be discussed later. However, they may react even at body temperature, as will be shown later.

The following case report illustrates occasional difficulties due to such irregular agglutinins. An anemic patient with a history of periodic hemorrhages from the gastrointestinal tract, the exact nature of which was not established at the time of this study and who had previously received nineteen uneventful blood transfusions, needed another transfusion. It was found in the laboratory of Dr. A. S. Giordano of South Bend, Ind., that the patient's blood was of group A but that his serum clumped red cells of a donor of group A and of several donors of group O.

The red cells of the patient were determined as belonging to subgroup A_1 and as Rh positive. The determination of the subgroup was done according to the method of the author⁶ in which an immune serum is obtained from rabbits treated with boiled red cells of sheep. This serum differentiates the subgroups A_1 , A_2 , A_1B and A_2B very sharply by clumping red cells of all subgroups in lower dilutions and only A_1 and A_1B in higher dilutions. The dilutions to be used have to

be determined by titrations. High titered immune serums are easily produced and keep well.

From the accompanying table it is apparent that the reason for the difficulty in blood grouping was the presence of the α_2 agglutinin. This agglutinin clumped cells A_2 and O equally strongly not only at room temperature but also at 37 C. The titer was 1:3 at room temperature and 1:15 at body temperature. The titer of the anti B agglutinin was 1:12. Another specimen obtained about one month later reacted similarly.

Adsorption of the serums with A_2 cells removed agglutinins for A_2 and O cells and adsorption with O cells had the same effect. It is of interest that the α_1 agglutinin reacted at body temperature, while as a rule it reacts only at lower temperatures. Only a donor of subgroup A_1 would be suitable for this patient.

Reaction of Patient with α_2 Isoagglutinin

		Serums								
		Group			Sub grouping *			Human Anti Rh

Result Patient's serum (P) has α in addition to anti B Patient's blood formula A ₁ Rh positive anti B α										

* Subgrouping serum = immune serum produced by injections of boiled sheep blood.

+ Indicates presence of agglutination — absence of agglutination.

The α_1 and α_2 isoagglutinins are not in disagreement with the law of Landsteiner as quoted, since the evidence favors the concept of a qualitative difference between A_1 and A_2 .

Another type of difficulty and the manner in which it was solved is presented in the report of the next case.⁶ A 2½ year old Negro boy with tuberculosis and a positive complement fixation reaction for syphilis required a blood transfusion, but there were difficulties in selecting a suitable donor because the boy's serum clumped red cells of his own group and of group O. Dr. Elizabeth Schurmer kindly submitted the blood to me. I found that the patient's red cells were of group A, subgroup A_1 , type N and Rh positive and that his serum clumped red cells of subgroups Λ_1 and A_2 and of group O rather irregularly. The bloods of some individuals of these groups and subgroups were clumped and those of others were not. There was no extreme difference between the reactions at 0 to 5 C and at 22 C, but at 37 C the reactions were weaker.

though distinct. It was found that all the cells that were agglutinated by the serum had one thing in common: the factor M. By proper adsorptions it was demonstrated that the formula of the blood was A_1N Rh positive anti B anti M. It is characteristic for the M and N blood types that there are no normal agglutinins for them in human serum. Only 4 instances of anti M agglutinins in man have been reported previously: the latest by Wiener and Forer.⁷ Two specimens of blood were obtained subsequently, one eight months and the other twelve months after the first examination. The first specimen still contained the anti M agglutinins, though in a lower titer; the specimen obtained after twelve months showed a minute trace detectable only at room temperature but not at body temperature. The parents were both of type N and had no anti M agglutinins.

The origin and nature of the irregular a_1 , a and anti M isoagglutinins are unknown, just as are the origin and nature of the so-called normal isoagglutinins anti A and anti B, although there is no lack of hypotheses attempting to explain the origin of the latter.

The next group of irregular isoagglutinins is the cause of serious and even fatal, now frequently preventable, blood transfusion reactions. They are due to isoimmunization of a person by a blood factor which is absent from his blood and is introduced parenterally. The story of the discoveries of the Rh factor by Landsteiner and Wiener,⁸ of the role of isoimmunization by this factor in intragroup transfusion reactions by Wiener,⁹ of the isoimmunization by the Rh factor in pregnancy and of its role in transfusion reactions in pregnancy and in the pathogenesis of erythroblastosis fetalis by Levine¹⁰ is one of the notable events in recent scientific developments. The hypothesis of Levine was confirmed by Potter, Davidsohn and Crunden.¹¹

The existence of qualitative differences in the Rh agglutinogens in human Rh positive blood was first established by Wiener,¹² similar differences in the Rh property in the bloods of man and the rhesus monkey were reported by Landsteiner and Wiener.¹³ Toharsky and I¹⁴ furnished experimental evidence to the effect that the Rh factor in man consists of several fractions and that the factor in man and in the rhesus monkey are not identical.

Related to this group are rare instances of isoimmunization of persons of subgroup A_1 who receive the blood of subgroup A_2 , or vice versa. That subgroups A_1 and A_2 , A_1B and A_2B are not always compatible was claimed by some writers and denied by others.⁵ A recent publication by Wiener¹⁵ records instances of immune isoagglutinins against subgroups A_1 and A_2 , as contrasted with the rare, normal, not immune a_1 and a_2 agglutinins.

Cold agglutinins are another form of irregular isoagglutinins. They react as a rule with red cells of all groups, even with the cells of the same individual. In most instances they are active only at ice box temperature, but sometimes even at 20 to 22 C (room temperature), and then they frequently display a certain degree of specificity and react only with the cells of some persons. This form of agglutination is a true agglutination, a true antigen-antibody reaction, as contrasted with pseudoagglutination, the most common example of which is rouleau formation. The antibody responsible for cold agglutination can be removed by adsorption. With pseudoagglutination, treatment of serum with red cells does not alter the ability of the serum to form rouleaux.

The titer of cold agglutinins may be fairly high at ice box temperature but it drops rapidly as the temperature rises and is only rarely demonstrable at 20 C and still higher at 37 C. It may be a source of error in blood grouping and in cross matching tests, as in the case of an 8 year old boy of group A with tuberculosis of a hip who had received several blood transfusions without reactions. One day his blood was compatible with donors of group A but suddenly the next day it was found incompatible with that of several donors of groups O and A, among the latter was one who had given blood to the patient on two previous occasions. Dr. A. S. Giordano sent me the blood of the patient and of the donor who had been compatible on a previous occasion and who became suddenly incompatible. Both were found to be of subgroup A_2 . The donor's serum showed no abnormalities, but the serum of the patient clumped indiscriminately red cells of all groups and also the cells of the donor and the patient's own cells at 0 to 5 C. At 22 C the serum behaved similarly but did not clump its own cells and the cells of the donor, whereas at 37 C it behaved as would be normal for its group. This was then an instance of cold agglutinins of a rather wide thermal range leading to difficulties in cross matching tests. The examination at 37 C cleared up the difficulty, as it does in most instances. The failure of the serum to clump the cells of the donor at 22 C, although it did clump the cells of the same donor twenty-four hours earlier in South Bend, can be explained by deterioration of the cells in transport, which is known to decrease their sensitivity.

It is generally denied that so-called cold agglutinins can be responsible for blood transfusion reactions. I have studied instances of such reactions in which all other possible causes were eliminated but in which strong cold agglutinins reacting at room temperature were present. In some instances special conditions like abnormalities in the blood of the patient were observed. In a recent transfusion reaction the connection between cold agglutinins and a hemolytic reaction seemed sug-

gestive. A $1\frac{1}{2}$ year old girl, a patient of Dr. H. G. Poncher, who is separately reporting this case with its many unusual features, suffered from hemolytic jaundice. She was of group O and received several uneventful transfusions but had a severe hemolytic reaction with oliguria following a transfusion with blood of the same group selected with meticulous care. Examination by me showed that the patient was Rh negative and had anti Rh agglutinins, and the donor whose blood caused the reaction as well as several of the previous donors was Rh positive. This then was an example of isoimmunization of an Rh negative person by previous transfusions of Rh positive blood. The child recovered from the reaction and received during the following month repeated transfusions from carefully selected Rh negative donors. The child had received altogether 2500 cc. of Rh negative blood without any untoward reactions when one day after the injection of about 250 cc. of Rh negative blood, she became pale, trembling and lethargic, had severe chills, her temperature rose to 105 F. in one hour and two to three hours afterward she had a definite hemoglobinuria. The child recovered. The record showed that the child's serum had cold agglutinins for the cells of the donor reacting strongly at 5 C and weakly but distinctly at 22 C but not at 37 C. The blood of the donor was kept in the ice box for twenty-four hours and then at room temperature approximately forty minutes before the transfusion was started. The blood was given at the rate of 30 to 35 drops a minute.

It seems to me that with cold agglutinins of the wide thermal range present in the patient's blood and clumping the blood of the donor in the test tube at 22 C and with the transfused blood having a temperature probably lower and certainly not higher than room temperature the conditions were present for a hemolytic reaction.

It is possible that changes in the condition of the red cells may be a factor which can influence the action of the so-called cold agglutinins. It is of interest that Landsteiner and Witt considered that possibility in a paper published in 1924¹⁶. The opinion that agglutinins acting at lower than body temperatures may be disregarded is contradicted by the practice of pretransfusion tests in which blood grouping and cross matching tests are done at room temperatures, and conclusions are drawn from these tests regarding a process that takes place at body temperature.

I am fully aware of the fact that, according to the prevalent opinion, so-called cold agglutinins play no part in untoward transfusion reactions. However, it is well to remember that this opinion goes back to a time when stored blood kept in refrigerators was not used for transfusions and when the occurrence of so-called cold agglutinins of a rather wide thermal range of reactivity and of a limited specificity was not known. I am not at all certain that statements in recent publications to the effect that blood stored in refrigerators may be injected without any attempt to raise its temperature should be endorsed as a safe procedure.

There is a special form of cold agglutinins known as autoagglutinins and found occasionally in patients with diseases of the liver and of the blood vessels, in typho-anosomiasis and in other diseases. There are instances

of this type of antibody in persons free of any evidences of disease. I studied recently the blood of a woman with a condition resembling Raynaud's disease. The abnormality of the blood became apparent when it was found impossible to do a blood count because the cells clumped in the diluting fluid. The serum of the patient agglutinated cells of all groups including her own red cells at ice box temperature and at 22 C but behaved at 37 C like a normal serum of group B. The same was true for the patient's red cells, which were clumped at the two lower temperatures even when suspended in saline solution. When the cells of the patient were washed three times with isotonic solution of sodium chloride they lost their abnormal behavior.

Wiener¹⁷ reported recently an observation of autoagglutinin reacting even at body temperature.

The fourth type of irregular isoagglutination is due to action of certain bacteria on red blood cells. It is known as the Thomsen phenomenon¹⁸. A variety of bacteria, most of them nonpathogenic, were found by Friedenreich and others to bring about a change in red cells making them panagglutinable which means that they are clumped by serums of all groups including serum of group AB which normally lacks isoagglutinins and even by the serum of the same individual. According to Thomsen this irregular form of isoagglutination is due to a change in the red blood cells through which a latent agglutinin becomes manifest and which reacts with an agglutinin normally present in all serums. This source of error in blood grouping is serious because the change may be completed within eight hours after contamination if the blood is kept at room temperature and may occur even at ice box temperature, though after a longer interval. The contaminating bacteria capable of such action are probably fairly common. The surest way to avoid this source of error is to observe aseptic technique, to use only fresh cell suspensions and to keep them in the ice box when not in use.

The fifth and last group of irregular isoagglutinins have been described recently by Toharsky and me¹⁹ as bacteriogenic hemagglutinins. We isolated from a contaminated typing serum a gram-positive bacterium identified as belonging to the large group of diphtheroids. The bacterium was designated as *Corynebacterium hektoeni*. It imparts to the serum and plasma new hemagglutinating properties and makes them panagglutinating in fairly high titers at 22 C and 37 C. Not only the bacterium but also the filtrates of its cultures have the same transforming ability. In addition to the change in the serum, the bacterium and its cultures make red cells panagglutinable by serums of all groups, thus producing the previously mentioned so-called Thomsen panagglutination phenomenon. Bacteriogenic hemagglutinins are of interest as a source of error in blood typings and as a potential danger as a contaminant of stored serums and plasma. The danger is enhanced by the fact that the keeping of typing serum or of therapeutic serum and plasma in refrigerators does not prevent the growth of the responsible bacterium.

In eliminating typing errors due to cold agglutinins, one is helped by the failure of most of them to react at 37 C, but this does not help one in recognizing bacteriogenic hemagglutinins because they react readily at body temperature. Here too the best way to eliminate the source of error is to type the serum as well as the red cells and to remember that typing of red cells is only half of the job. Serum with bacteriogenic hemagglutinins will clump red cells of group O, which are normally not agglutinated by any serum. When one has reason to suspect that bacteriogenic panagglutination has developed, the way to prove it is to test the cells with serum of the same individual or with serum of group AB known to be free of cold agglutinins and to type the serum of the unknown blood specimen with red cells of known groups.

Several bactericidal and bacteriostatic agents have been found which prevent development of bacteriogenic hemagglutination.

ABSTRACT OF DISCUSSION

DR PHILIP LEVINE, Newark, N J. Recent studies indicate that about 90 per cent of intragroup transfusion reactions following isoimmunization either by repeated transfusions or by fetal blood during pregnancy occur in Rh individuals. Unfortunately not all cases can be detected by the demonstration of anti Rh agglutinins. In many cases it must be assumed that the anti Rh antibody is fixed to the tissue cells of the reticuloendothelial system. To prevent intragroup transfusion accidents, all Rh patients should receive blood from Rh donors. Also the modified cross matching test, i.e. incubation of patient's serum and donor's cells at 37 C for fifteen to thirty minutes should be carried out. Whenever anti Rh agglutinins could be demonstrated, they frequently behave like warm agglutinins in contrast to those which react best at 20 C or lower temperature. Occasionally an Rh patient immunized by the Rh factor may have several atypical agglutinins, as demonstrated by varying specificities at different temperatures. In such cases the compatibility tests should be carried out at 37 C, while incompatibilities detectable at lower temperature are probably of less significance. Rarely, however, atypical agglutinins acting at low temperature may cause transfusion reactions. In my opinion these are apt to occur in patients immunized either by repeated transfusions or by the fetus, but by blood factors other than Rh. In these instances, as in the exceptional cases of Wiener and Peters, i.e. cold anti Rh agglutinins, one cannot be certain whether the demonstrable antibodies or tissue antibodies are responsible for the transfusion reactions. This view does not conflict with the claim of Landsteiner and Levine that the atypical agglutinins present in 3 per cent of all normal individuals probably do not cause transfusion reactions. In these instances the atypical agglutinins inactive at 37 C are physiologic for these individuals, in contrast to the atypical immune agglutinins mentioned. An appeal can be made to abandon the nomenclature of the blood groups by numbers. The letters O, A, B and AB indicate the correct theory of two dominant factors A and B and the recessive property determining group O. In cases of disputed paternity, tests are carried out for the presence or absence of the factors A, B, M, N and, in the future, also Rh. The factors A and B may be of importance also in causing fetal death. Accordingly, a discussion of these applications can be intelligible only if the terminology by letters is employed.

DR FREDERIC FELDMAN, Brooklyn. Had the patient with the anti O agglutinin received transfusions with O blood? Had the O acted as an antigen? Does the same apply to the case with anti M agglutinin?

DR ISRAEL DAVIDSOHN, Chicago. The patient that I referred to did not belong to blood group O but to A₁. He had received several blood transfusions before, both of the same blood group

and of group O, without any untoward reactions, when it was found in the course of a cross agglutination that his serum clumped cells of his own group and of group O. This observation confirms exactly what Dr Levine was telling us. The irregular isoagglutinins α_1 and α belong to the group of cold agglutinins. After repeated transfusions or possibly of some infection, irregular isoagglutinins may appear. I have observed that the rise occurs in the course of infections even without immunization by means of blood transfusions. It is not known whether these agglutinins are entirely new or whether their titer rises and they become detectable, having been previously below the threshold of detectability. A similar mechanism may have operated in the case of the anti M agglutinin. That child did not receive any transfusions before. It is not a familial case. Both parents were investigated and they did not have anti M agglutinins. The origin of these anti M agglutinins is unknown.

Clinical Notes, Suggestions and New Instruments

BERIBERI HEART IN A 4 MONTH OLD INFANT

(WITH FOUR YEAR FOLLOW UP)

HENRY RASCOFF M.D. BROOKLYN

Infantile beriberi has rarely been reported in the continental United States. Waring¹ in 1928 recorded the occurrence of this disease in a 2 month old child with findings of cardiac hypertrophy, loss of knee reflexes, hepatic enlargement and finally heart failure. A poor nutritional background was given as the etiologic factor. Other observers² have mentioned the possibility of beriberi being one of the causes of enlarged hearts in occidantal infants.

The following report is of an infant that for two months had been on a limited diet of boiled human milk and subsequently developed an enlarged heart, which diminished in size with thiamine hydrochloride therapy.

REPORT OF CASE

R. S., a white boy, was born at the Beth El Hospital on Feb. 19, 1938 two weeks before term and of normal spontaneous delivery. The stay in the hospital was uneventful, and he was discharged on the tenth day weighing 2 ounces (55 Gm) above the birth weight of 5 pounds (23 Kg). Shortly after reaching home the infant began to vomit, the next day diarrhea set in. For the following three weeks various formulas of sweet and acid milks were given with but little success. The vomiting and diarrhea persisted in varying degree and on March 20 the child was hospitalized.

On admission the infant weighed 5 pounds 8 ounces (25 Kg). It was somewhat malnourished and dehydrated, but the rest of the examination was not remarkable. Clasis and venoclysis of 5 per cent dextrose in isotonic solution of sodium chloride were given. When the vomiting and diarrhea were controlled, feeding by mouth was begun with gradually increasing amounts of dextrose water. This was supplemented by and finally replaced by protein milk to which had been added 5 per cent of a preparation of maltose and dextrin. However, when a sufficient amount of formula calculated to the child's needs was given, the stools once more became watery and frequent. Parenteral feeding was again resorted to, and in addition a transfusion of 75 cc of citrated blood given. This time human milk was introduced as the food of choice. The infant seemed to tolerate this and was discharged on April 15 on a diet of human milk boiled for thirty minutes, 50 mg of ascorbic acid and 3 drops of vitamin D daily. The weight of the child at this time was 5 pounds 14 ounces (26 Kg).

² Abt I A. The Child's Heart in Avitaminosis. *Am J Dis Child* 50 455 (Aug) 1935. Kugel and Stoloff¹⁰ Hoobler⁷

Shortly after reaching home, the infant developed an upper respiratory infection and for two weeks there were bouts of diarrhea, which were again controlled by the feeding of boiled milk. For the ensuing six weeks the child gained weight on this form of milk and made satisfactory progress.

At the age of 4 months the infant suddenly became dyspneic and cyanotic. The temperature was not elevated. Examination of the chest revealed that the breath sounds were exaggerated but no rales or bronchial breathing was elicited. There were no abnormal reflexes, nor was there edema of the extremities or dependent parts. The weight at this time was 10 pounds 13 ounces (4.9 Kg). X-ray examination of the long bones gave normal results.

Physical and roentgen examination of the heart revealed a general cardiac enlargement (fig 1). The heart sounds were only fair in quality. The electrocardiographic tracing did not show any abnormalities in conduction or in the contour of the individual waves, only a slight tachycardia of sinus origin. As the result of consultation with Dr. Bela Schick and Dr. Leo M. Taran, it was felt that in view of the apparent vitamin B₁ deficient diet we might be dealing with a beriberi heart. Accordingly, the child's daily diet was supplemented with 6 mg of thiamine hydrochloride. Within two weeks the cyanosis and dyspnea were gone. At the age of 6 months the child was able to tolerate a formula of whole cow's milk and maltose with dextrin, precooked cereal and a few simple vegetables. At the age of 18 months there was still X-ray evidence of cardiac enlargement. However, the child was developing satisfactorily. His weight at this time was 31 pounds (14 Kg) and he was 32 inches (81 cm) tall.

At the age of 4 years the child is in excellent physical condition, weighing 48 pounds (22 Kg) and measuring 43 inches (109 cm) in height. X-ray examination of the cardiac shadow reveals it to be within normal limits (fig 2).

COMMENT

Fehily³ reported from Hong Kong that infants fed milk of mothers suffering from B₁ avitaminosis showed signs of infantile beriberi. These signs were grouped as acute subacute and chronic. The acute form was characterized by cyanosis, dyspnea, rapid pulse and often sudden death; the mortality rate being 93 per cent. Children dying from the acute form responded in short order to tiki-tiki (extract of rice husks). She noted too that the milk from beriberi mothers was not only deficient in thiamine but gave a "peroxidase negative" reaction.

Peroxidase is an enzyme normally found in fresh milk and blood of mammals. It is destroyed by heat and is absent in certain conditions as in the secreted milk of mothers suffering from beriberi. Its presence or absence is noted by the Arakawa reaction which is based on the "oxidation of substances of a phenolic nature to colored compounds by a peroxidase in the presence of a ferment peroxidase, which catalyzes the reaction."³

A "peroxidase negative" milk of mothers presenting signs of beriberi is an indication of B₁ avitaminosis, according to Fehily. Kendall⁴ has shown that boiled human milk is low in thiamine content. These two features of milk from beriberi mothers, i.e., low thiamine hydrochloride content and "peroxidase negative"

Fig 1—Generalized cardiac enlargement at the age of 4 months

milk, were characteristic of the boiled human milk fed infant. Another predisposing factor for the development of infantile beriberi in this child was the recurring prolonged diarrhea. It has been demonstrated that the poor utilization of food substances, such as in chronic diarrhea, plays a role in the etiology of this condition.⁶

The basis for the development of subclinical or clinical beriberi is often present in early infancy. The dietary of the average infant during the first three months of life is composed of human or cow's milk supplemented with carbohydrate, orange juice and some form of vitamins A and D. This diet is deficient in vitamin B₁. When vomiting or diarrhea, both common in infancy, are present for any length of time the body is depleted of its vitamin reserve. In treating these gastrointestinal disturbances some form

Fig 2—Normal configuration of the heart at the age of 4 years

of boiled milk is usually given. Boiled milk, as previously noted, gives a peroxidase negative reaction and is low in thiamine hydrochloride. In view of this knowledge the dietary of the average infant should be supplemented with 100 international units of vitamin B₁ daily. When diarrhea or vomiting is persistent, the amount given should be many times this dose.

The group of heart conditions in infancy vaguely classified as idiopathic cardiac hypertrophy has been greatly reduced in recent years by the increased knowledge of the etiology and postmortem study of enlarged hearts in infancy. Scurvy,⁷ rickets,⁸ celiac disease⁹ and congenital anomalies¹⁰ have been found to be causative factors in this "idiopathic" condition. Infants suffering from cardiac enlargement of unknown origin should be given adequate doses of thiamine hydrochloride as a therapeutic test for beriberi heart.

One should also reexamine the sudden deaths attributed at present to status thymicolymphaticus. These may be the result of the acute form of beriberi, especially may this be true when a previous history reveals a diet deficient in vitamin B₁.

SUMMARY AND CONCLUSIONS

1 In a case of beriberi heart in a 4 month old infant the diagnosis was made clinically and therapeutic response was noted with thiamine hydrochloride.

2 The daily diet of the average young infant is deficient in thiamine hydrochloride and should be supplemented with vitamin B₁. In cases of gastrointestinal disturbances the vitamin B₁ intake is to be increased.

3 Some cases at present diagnosed as idiopathic cardiac hypertrophy, or deaths attributed to status thymicolymphaticus may be caused by infantile beriberi.

5 Dr. Irving Greenblatt of the chemistry laboratories of the Beth El Hospital found that several specimens of raw human milk which gave a positive peroxidase reaction on initial examination became peroxidase negative when subjected to heat or 78° C. for more than three minutes. Pasteurized milk gave a similar response but evaporated milk was peroxidase negative without further heating.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

MANY TYPES OF ANTIPNEUMOCOCCUS RABBIT SERUM HAVE APPEARED ON THE MARKET AND THE MULTIPLICATION OF THESE TYPES HAS BEEN SO GREAT THAT THE COUNCIL VOTED TO SPONSOR A REPORT TO CLARIFY THE STATUS OF THESE SERUMS FOR THE TREATMENT OF HIGHER TYPES OF PNEUMOCOCCIC INFECTIONS. DR. MAXWELL FINLAND AGREED TO PREPARE A PAPER ON THIS SUBJECT AND ACCORDINGLY HAS PRESENTED THE FOLLOWING STATEMENT WHICH THE COUNCIL HAS ADOPTED FOR PUBLICATION WITH APPRECIATION TO THE AUTHOR FOR THE EXTENSIVE WORK NECESSARILY ENTAILED IN THIS STUDY.

AUSTIN E. SMITH, M.D., Secretary
COUNCIL ON PHARMACY AND CHEMISTRY

THE PRESENT STATUS OF THE HIGHER TYPES OF ANTIPNEUMOCOCCUS SERUMS

MAXWELL FINLAND, M.D.

BOSTON

Antipneumococcus serums from rabbits have now been accepted by the Council for types I, II, III, IV, V, VII, VIII and XIV.¹ An evaluation of the other types of antipneumococcus serums, which for convenience will be called the "higher types,"² involves a consideration of the following problems: (1) the present status of the pneumococcus types, particularly as it concerns serologically related types, (2) the relation of the higher types to disease in general and to pneumonia in particular, (3) the efficacy of antipneumococcus rabbit serums in the treatment of the pneumonias associated with pneumococci of these types, (4) the status of specific antiserum therapy for pneumonia in relation to the use of effective sulfonamide compounds (a) as a supplement or (b) as a substitute for the drugs, and (5) the use of serums in the treatment of focal pneumococcic infections, particularly meningitis and peritonitis.

It may be stated at the very outset that, from the point of view of adequate, clean-cut and conclusive data which will withstand analysis by statisticians or by intelligent critics or skeptics, no solution to these problems can be expected at the present time. Nor is it likely that proper data will be forthcoming in the near future that will be any more helpful. Nevertheless it seems advisable to review briefly the available facts and to try to arrive at some intelligent attitude and practical approach to the problem of the use of the higher type antipneumococcus rabbit serums.

PRESENT STATUS OF THE CLASSIFICATION OF PNEUMOCOCCI INTO TYPES

In 1932 Cooper and her co-workers³ separated the unclassified strains of pneumococci, which had previously been included in group IV, into twenty-nine new types designated as types IV to XXXII. Only

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital and the Department of Medicine, Harvard Medical School.

1 Antipneumococcus Serums, Council on Pharmacy and Chemistry, J. A. M. A. **115**: 460-461 (Aug. 10) 1940; **116**: 2597 (June 7) **117**: 1264 (Oct. 11) 1707 (Nov. 15) 1941; Antipneumococcus Serum (Rabbit) Type XIV, *ibid.* **117**: 2073 (Dec. 13) 1941.

2 All types other than I, II and III have usually been included in the higher types. Since the present discussion is limited mostly to those types for which antisera are not yet accepted by the Council, it seems appropriate and convenient for the purpose at hand to exclude all of the accepted types from the category of higher types.

3 Cooper, Georgia, Rosenstein, Carolyn, Walter, Annabel and Peizer, Lenore. The Further Separation of Types Among the Pneumococci Hitherto Included in Group IV and the Development of Therapeutic Antisera for These Types, J. Exper. Med. **55**: 531-554 (April) 1932.

a small percentage of strains that they had isolated in New York City did not fall within these types. A few cross reactions were noted, particularly between types II and V, III and VIII, VII and XVIII and XV and XXX. Type XXVI was found to react with the original type VI to such an extent that the former was designated VIb and the latter VIa. Strains of these types have since been included under the single designation type VI by most workers. The original type XXX is also usually eliminated because of the difficulty in differentiating it from type XV. With these two changes, the Cooper classification has been adopted and used for clinical and epidemiologic purposes throughout the world.

Pneumococci of almost all these types have been found wherever sufficient numbers of strains from different sources have been studied. The percentage distribution of these types in various pathologic conditions and in normal individuals has varied in different localities, and at different times in the same place. The percentage of untyped strains which failed to react with antisera for the Cooper types likewise varied considerably. In South Africa, where a separate and equally extensive classification had been in use, it was found that only two of the Cooper types did not have counterparts in the local types and, conversely, only two of the South African types were not represented in the Cooper classification, which has since been adopted there.⁴

The various pneumococcus types are generally considered to be quite stable. Transformation of one type to another has been accomplished both in vitro and in experimental animals.⁵ To do this, however, it has been necessary first to convert the original type specific pneumococcus by special procedures from the so called smooth and virulent (and presumably pathogenic) form to the avirulent and non-type specific rough variant. The latter is then grown, either in vitro or in the peritoneal cavity of a mouse, in the presence of smooth killed organisms of the type to which it is to be converted. The type specific polysaccharide may be used in place of the killed organisms for this purpose. It is not known whether similar transmutations take place in nature, but it seems highly improbable. In general, type specific pneumococci obtained from the nasopharynx or other sources in the absence of manifest disease appear to be about as stable with respect to their type specificity as those obtained from active infections.

Although the Cooper classification has proved adequate for most purposes, there still remained a significant number of untyped strains. The proportion of unclassified strains has varied with the type of material under study and has differed widely in various localities and at different times in the same region or even in the same laboratory. As interest in the use of antipneumococcus serums increased (before effective sulfonamide drugs became available) various investigators became concerned over the diagnostic and therapeutic difficulties involved in the management of individual sick patients or groups of cases. New types were discovered when inordinate numbers of untyped strains

Hyg. **27**: 113-159 (Jan.) 1928. Dawson, M. H. Interconvertibility of R and S Forms of Pneumococcus. J. Exper. Med. **47**: 577 (April) 1928.

from patients with severe pneumonia or meningitis were encountered in rapid succession. For example, at the State Serum Institute in Copenhagen, diagnostic serums were prepared against two hitherto unknown strains. In the course of half a year one of these types was demonstrated in 31 patients, including 2 with meningitis, and in 9 normal individuals, the second type was found in 72 patients and in 10 normal individuals.⁶

In addition to therapeutic serums for some of the types were used, some clinicians were struck with the fact that certain patients failed to show a beneficial response to what seemed to be adequate doses of antiserum. Investigations in some of these cases revealed that the failures were due to the fact that the causative organism was a pneumococcus which was serologically related to but not identical with the strain used in producing the therapeutic antiserum. Better results were obtained when specific serum for the newly discovered type was used.⁷ Other types were discovered because of cross reactions in horse or rabbit diagnostic serums.⁸ Such cross reactions were particularly frequent in agglutination reactions with horse serums, but they were also noted when the Neufeld capsular swelling reaction with diagnostic rabbit serums was used for typing. These facts led to a continued interest in the classification of pneumococci, which resulted in the recognition of many entirely new types and a number of types closely related to those previously classified.

In 1940 Kauffmann, Mørch and Schmitz⁹ at the Danish State Serum Institute determined serologically twenty new types of pneumococci in addition to the thirty Cooper types. They worked out the antigenic components of ten groups, each of which consisted of from two to four serologically related types, and indicated which serums were necessary to establish the specific type diagnosis. The importance of having type specific antibodies for therapy has already been mentioned. In discussing the significance of their new types for diagnosis and treatment the Danish workers suggested that, for practical purposes, polyvalent serums could be prepared for the related types. Bjoerneboe¹⁰ of the same laboratory showed that equally high titers of antibody could be obtained for each of the related types in this manner. He demonstrated it clearly for type VII and its three related types, for example. It is not known, however, whether the efficacy in human therapy in this respect parallels the mouse protective or other antibody titers. If this is assumed to be the case, then the practitioner need not be burdened with the intricacies of the many related types. He would then be concerned in diagnosis only with the main group or type and would obtain a therapeutic serum which would include antibodies for all the known related types.

Walter and her associates¹¹ of the Bureau of Laboratories of the New York City Department of Health described seventeen new types of pneumococci, of which nine were distinct from types I to XXXII and eight showed definite cross reactions with other types and were therefore called subtypes. These types were correlated with those of other workers and a terminology was recommended which included their own new types and those of Kauffmann. The original type XXVI of Cooper was officially omitted and types VIa and VI b were considered identical and the letters omitted. The original type XXX was included as type XVa and a new strain was designated as type XXX. Including one new type and six new subtypes of Kauffmann's, Walter's classification comprised a total of forty distinct types and fifteen subtypes.

Mørch¹² continued the work at the Copenhagen laboratory and subsequently presented eighteen additional types. He correlated his types with those of Walter and Kauffmann and their respective co-workers and extended the latter's schema for the diagnosis of related types on the basis of the capsular antigenic components. He also presented a method of preparing serums for determining and controlling the titer of each of these components. This study raised the total number of pneumococcus types to sixty-eight, of which forty-one are distinct types numbered I to XLII (excluding XXVI). The remaining twenty-seven types are included in fourteen groups, each consisting of from two to four related types. Mørch again pointed out the importance of having antibodies against all the antigenic components in therapeutic antisera. He also emphasized the practicability and advisability of using mixed vaccines composed of pneumococci belonging to a group of related types in the immunization of animals for this purpose. Epidemiologically, however, the individual types within the groups of related types may each become significant under special circumstances.

In their most recent report to the American Public Health Association, the Standard Methods Committee¹³ was of the opinion that the classification of pneumococcus types should be not only scientifically correct but, if possible, should be readily understood and applicable to the epidemiologic and clinical purposes for which pneumococcus typing is most generally employed. Conceivably, at least some of the types are not of sufficient importance to warrant their inclusion in routine public health and hospital practice. Should this prove to be true, they indicated that an abbreviated routine might prove desirable.

SIGNIFICANCE OF THE HIGHER TYPES OF PNEUMOCOCCI IN DISEASE

The work on the separation of types among the pneumococci has had as its ultimate or most important objective either the possibility of preparing effective specific antisera for the treatment of patients or, as in the South African work, the development of vaccines for the prevention of pneumococcal infections. Therapeutic antisera were prepared in the early work

at the New York City Laboratories almost as soon as the new types were established and shown to be fairly prevalent.¹⁴ The necessity of using horses for immunization limited this phase of the work considerably. Further diagnostic and therapeutic serums were then prepared with strains from severely ill patients which failed to agglutinate or showed atypical reactions with antiserums for available types.³ In the accounts given by Cooper and Walter and their co-workers,¹⁵ the sources of the strains used in establishing the new types are given. Each of the new types included some strains isolated from blood cultures or autopsy material of patients with pneumonia, or from spinal fluid of patients with meningitis.

As already mentioned, the more recent types resulted from work undertaken because of diagnostic and therapeutic difficulties in severely ill patients. The use of rabbit serums, both in diagnosis and in treatment made possible a more rapid extension of the work than was feasible when horses were employed for the preparation of antiserums. Some of the new types were soon shown to be quite prevalent, as evidenced by the first two types isolated at the Danish Serum Institute.⁹ A new strain identified in our laboratory¹⁶ and later called type XIa¹¹ was found at the Boston City Hospital in more than 25 cases in one season. The new type XXXIII, which gives cross reactions with type IX antiserums, was identified at about the same time in New York City¹⁷ and in Copenhagen⁶ and was also isolated by us from patients with pneumonia, meningitis and peritonitis who failed to show a favorable response to treatment with type IX therapeutic antiserum. In the New York City laboratory during the first five months of 1940, among 2,591 specimens from patients with pneumonia the two new types XXXIII and XXXV were found forty-five and seventy-one times respectively, and the two new subtypes XIa and XIb were found thirty-three times and fifty times respectively. These four new types each occurred more frequently than any of twelve different types among those included in the Cooper classification.¹⁸ Except for type XXXIII, however, very little additional data concerning the new types are available, and there is almost no information about the efficacy of therapeutic antiserums in the treatment of pneumonia due to these new types or subtypes. The rest of the discussion will therefore be concerned primarily with the original Cooper types.

In cases of pneumonia the etiologic role of any pneumococcus that is recovered is not always simple to determine, particularly if the only source of that organism is the sputum or a throat culture. Under such conditions a knowledge of the relative frequency with which various types of pneumococci are found in lobar or atypical pneumonias, in certain focal infections and in the nose and throat of normal persons is of some help. In patients with pneumonia, the relative frequency with which the different types of pneumococci are found in blood cultures, in cultures obtained from the lung during life or at autopsy or in purulent focal complications, and the development of specific antibodies during

recovery for types found in the sputum aid in assessing their etiologic significance. A brief review of some of the available data concerning a few of these points, particularly in relation to the "higher" types of pneumococci is therefore pertinent.

All of the types from I to XXXII have been found with varying frequency in cases of pneumonia, in a variety of focal infections and in normal persons without apparent disease.¹⁹ Types IV, V, VII and VIII are usually the most frequent of the Cooper types found in cases of typical lobar pneumonia. In atypical or bronchopneumonias the distribution of types is more like that found in normal persons.²⁰ In the pneumonias complicating pregnancy and the puerperium, the incidence of pneumococcus types is essentially the same as in cases of primary lobar pneumonia,²¹ while in those complicating operations and trauma the type distribution is intermediate between that found in normal persons and that found in patients with lobar pneumonia.²² In the pneumonias of infants and children, type XIV predominates and types VI and XIX are frequent.²³ The latter types are also very frequent in normal persons.²⁴

Multiple types of pneumococci are often found in sputum and sometimes from other sources in patients with pneumonia.²⁵ This is particularly true of infants and children and has been recognized more readily since the introduction of the Neufeld method of direct typing. These multiple types (or the finding of a pneumococcus and some other organism) may represent either a true simultaneous infection or consecutive infections or, most commonly, one of the types is etiologic and the other is a normal inhabitant of the respiratory tract and not involved in the infection.²⁶ Some types, when found under such conditions almost always prove to be etiologic, others only rarely prove to be related to the disease, while still others occupy an intermediate position.

Bullowa²⁷ listed 225 strains obtained from adult cases of pneumonia with multiple infections. He classified these strains into those which occurred as definite pathogens, i. e. in blood cultures, chest pus or lung suction, and those which were indeterminate or possibly nonpathogenic and were obtained only from sputum. There were 114 strains in the former and 211 in the latter. Among the pathogenic strains, 92 were of the "accepted" types I to VIII (excluding VI) or XIV, while 22, or 10.5 per cent, were "higher" types. Among the possible nonpathogens, 52 per cent were of "higher" types. Of the 193 strains of "Council accepted" types, 48 per cent were definite pathogens, while of the 132

"higher" type strains only 16.7 per cent were obtained from blood culture, pleural fluid or lung suction.

Andrews²⁸ divided the pneumococcus types found in the pneumonias of infants and children into three etiologic groups. In group A, she included types I, V, XIV and XXII and the less frequent types II, VII, X, XII and XVII. These types appeared to be causative in all patients with lobar pneumonia from whom they were recovered, they were associated with a high incidence of pneumonia in infected persons, a high mortality among infants and a pronounced tendency to disseminate among the members of the families of

dence in the families of patients with pneumonias due to other types or in families in which there were no cases of pneumonia. Finally, group C included the least active types III, VIII, XIII, XV, XVI, XIX, XX and XXVIII. These types appeared to be responsible for lobar pneumonia in very few patients in whom they were found, evidence for familial dissemination was uncommon and they were most often recovered from persons who were in contact with heterologous types. Differences in incidence of types, in the relation to lobar pneumonia and in their dissemination within family groups was also found to vary with age.

TABLE 1.—Relation of 'Higher' Types of Pneumococci to Pneumonia and Other Infections as Indicated by the Relative Frequency of Their Occurrence as Compared with the Types for Which Therapeutic Serums Have Been Accepted by the Council

Source of Cases	Source of Pneumococci	Number of Cases	Accepted Types (I II III IV V VII VIII XIV)		Higher Types (Remaining Types of Cooper ²)		Comment
			Per Cent Incidence	Per Cent Mortality	Per Cent Incidence	Per Cent Mortality	
New York State ²⁹ Illinois ³⁰ and Pennsylvania ³¹	All typed pneumococci pneumonias Fatal cases only	29 172 3 355	78.5 80.4	11.8	21.5 19.6	10.5	All Cooper types and XXVIII represented
Harkness ³² Bellevue ³³ and Boston City Hospital ³⁴	All typed pneumococci pneumonias (adults) Fatal cases Positive blood cultures	12 049 2 762 2 516	74.8 73.4 86.8	22.3 29.3	25.2 26.6 13.2	24.2 67.4	All Cooper types and XXVIII represented among the fatal and the bacteremic cases
			(Positive blood cultures in 24.2 per cent)		(Positive blood cultures in 10.9 per cent)		
Harkness Hospital (Bulldown)	Adult pneumonias lung suction	1 477	34.7		4.6		No pneumococci from remaining cases 7 of the higher types not represented
Boston City Hospital (Finland ³⁵)	Typed pneumococci pneumonias in adults Lobar pneumonias Atypical (broncho) pneumonias Primary pneumonias Secondary pneumonias	2 848 2 979 619 228 620	76.4 83.4 50.7 81.7 61.3	41.5 37.8 63.0 35.7 69.5	23.6 16.6 49.3 19.3 30.7	35.9 27.5 46.2 23.0 58.6	2 172 cases were of accepted types of these 15.3% were secondary 14.5% were atypical pneumonias 070 cases were of higher types of these 43.8% were secondary 4.1% were atypical pneumonias
	Cases with autopsy Lobar pneumonias Atypical pneumonias	654 394 290	76.6 91.9 55.9		23.9 8.1 44.1		524 cases at autopsy were of accepted types of these 30.9% were atypical pneumonias 160 cases at autopsy were of higher types of these 50.0% were atypical pneumonias
	Focal infections without pneumonia	243	74.5		25.5		
Five hospital series ³⁶	'Typed' pneumonias in infants and children	2 506	54.9		45.1		All Cooper types and XXVIII represented
South African (Ordman ³⁷)	Pneumococci pneumonias Inoculated cases Uninoculated cases	1 496 447 1 049	60.6 45.6 67.1		10.8 14.6 9.2		Remaining cases were of native types not represented in the Cooper classification three Cooper types were not represented
Collected cases (Hollander ³⁸)	Typed pneumococci meningitis	189	56.7		43.3		Excluding 71 cases of types not stated and 4 cases of type over XXII
England ³⁸ and Germany ³⁹	Pharyngeal cultures of healthy pneumococcus carriers	3 543	30.1		53.2		16.7% were negative I, XXII of the 30.1% accepted types almost half (14.9%) were type III

pneumonia patients having these types. Group B included types IV, VI, IX, XI, XVIII, XXIII, XXIX, XXX and XXXI, which were considered to be intermediate in their relation to pneumonia. These types were causative in many, but not all, of the children from whom they were recovered. In comparison with group A, these types were associated with a lower incidence of pneumonia among persons who harbored them, a lower mortality in infants, less evidence of dissemination among the members of the families of patients with these types and a relatively higher inci-

A similar attempt to classify the types with respect to pneumonia in adults would result in a considerably different alignment. For example, type IV would belong in group A, types III, VIII and XIV might well fit into group B and type VI would be in group C. There would undoubtedly be considerable variations, depending on the source of the material for such a classification and the kind of data available for evaluating the etiologic relationships. One would also expect appreciable differences in different localities and even at different times in the same region.

In table 1 is listed a group of miscellaneous pertinent data collected from various sources for the purpose of bringing out the relative frequency and significance

²⁸ Andrews, Elizabeth T. Lobar Pneumonia in Children. Differentiation of Recovered Pneumococci into Etiologic Groups and Their Familial Distribution. *Am J Dis Child* 5:4 1285 1310 (Dec) 1937.

of the "Council accepted" types, I, II, III, IV, V, VII, VIII and XIV, and the other or "higher" types of the Cooper classification. In a large series of "typed" pneumococcal pneumonias collected by the pneumonia control divisions of the departments of health of three large states (New York,²⁹ Illinois³⁰ and Pennsylvania³¹) the higher types accounted for 21.5 per cent of the cases. In another large series of such cases in adults from three municipal hospitals in New York and Boston (Harlem,³² Bellevue³³ and Boston City Hospital³⁴), 25.2 per cent were associated with higher type pneumococci. In both of these series types XV and XVI, and all of the types numbered beyond XX, each accounted for less than 1 per cent of the total of "typed" cases. Types X, XII and XIII each occurred in less than 1 per cent of the "state" cases but were each found in more than 1 per cent of the hospital cases.

The mortality in all the cases of the "higher" types was about the same as in the cases of the "Council accepted" types of each of these two series. This seems surprising since the higher types are usually considered to be "less virulent" and presumably less fatal. The following evidence lends support to such a belief: 1. Most of the higher types are definitely less virulent for mice.³⁵ 2. Positive blood cultures are less frequent in cases with pneumococci of the higher types and, likewise, higher types are relatively less frequent in bacteremic cases of pneumococcal pneumonia. 3. Higher types were relatively infrequent in cultures obtained directly from the pneumonic lung during life; in fact, seven of the higher types were not encountered in lung cultures from 1,477 cases.²⁷

A likely explanation of this paradox is found in the analysis of a series of cases from the Boston City Hospital, also shown in table 1. The proportion of these cases that were due to the higher types was about the same for the entire series and for the cases that came to autopsy and was similar, in turn, to that found in the two larger series already mentioned. The mortality in all the cases of the higher types was only slightly less than in the other cases and not considerably lower, presumably because of the following combination of circumstances: 1. There was an appreciably

lower incidence of higher types among the typical cases of lobar pneumonia and a relatively much greater proportion of these types in the atypical pneumonias. 2. There was a relatively lower incidence of higher types in the primary pneumonias and a much greater incidence among the "secondary" pneumonias, i. e. among the pneumonias complicating other serious illnesses. 3. The mortality was significantly lower in the pneumonias of the higher types, as compared with that of the "accepted" types, in all groups of cases, that is, in the lobar and the atypical pneumonias and in the primary and the secondary pneumonias. 4. The mortality in all the atypical pneumonias and in all the secondary pneumonias, however, was considerably higher than in the lobar and in the primary pneumonias, respectively, regardless of the pneumococcus types. 5. Also secondary and atypical pneumonias were about three times as frequent among the cases of the "higher" types as among those of the "accepted" types. It would thus appear that factors, presumably in the host, which predispose to the occurrence of secondary or atypical pneumonias are also responsible for the high mortality in the cases of the higher types in spite of the lesser virulence and invasiveness of these organisms.

In the pneumonias of infants and children³⁶ the higher types are about twice as frequent as in the pneumonias of adults. As already noted, types XIV, VI and XIX are particularly frequent in infants and children but are relatively infrequent in adults.

The South African cases listed in table 1 show the probable effect of prophylactic vaccination. The vaccines used were prepared from prevalent types of pneumococci and presumably contained few, if any, of the "higher" types. The incidence of the latter among the inoculated patients was appreciably higher than among the uninoculated patients. Contrariwise, the "accepted" types, at least some of which were included in the vaccines, were definitely less frequent in the inoculated patients.

The "higher" types accounted for about one fourth of the Boston City Hospital cases of purulent pneumococcal infections in patients without pneumonia. In Hollander's³⁷ collected series 43.3 per cent of 189 typed cases of pneumococcal meningitis were of the higher types. In our experience the latter types are relatively more frequent in cases of meningitis in the absence of pneumonia than when the meningitis occurs as a complication of a pulmonary infection.

Among healthy pneumococcus carriers, more than half of the strains of pneumococci identified by two groups of investigators were of the "higher" types; about 30 per cent were of the "accepted" types and approximately one sixth did not correspond to any of the Cooper types. All the Cooper types, however, were represented in each of the two groups of carriers. The distribution of individual types varied in the individual reports, although not widely, considering the numbers of cases and types and the many other factors involved. There were some striking discrepancies, however, as, for instance, in the case of type XVIII. This type

accounted for less than 1 per cent of the normal carrier strains of pneumococci in the English series³⁸ and 13.8 per cent of those in Gundel's³⁹ comparable studies.

The distribution of the individual types in five different groups of cases is shown in table 2. All the Cooper types are represented in each of the pneumonia groups and in the normal carriers,⁴⁰ but their incidence varied widely. Except for a few discrepancies, the distribution of types in cases of pneumonia was very similar in the state⁴¹ series and in the adult hospital cases,⁴² but the mortalities in the various types are consistently higher in the latter. This may be due chiefly to the fact that a large percentage of the cases in the hospital series occurred before the introduction of effective sulfon-

groups according to the incidence of bacteremia. The first group includes all the "accepted" types and, in addition, types XII and XXV. These may be considered the most invasive types, in more than one sixth of the cases of each of these types (17.4 to 38.7 per cent) the blood cultures are positive. In this group the mortality percentage was roughly about the same as the incidence of bacteremia. In the case of types I, II and V the relatively lower mortality rate may be explained in part by the use of effective serums in a large proportion of cases. The second group includes types IX, X, XVIII, XIX, XX, XXII, XXIII and XXIV, which were intermediate in their invasiveness. Between 8.6 and 14.5 per cent of the cases in each

TABLE 2.—Distribution of *Pneumococcus* Types in Pneumonia and in Healthy Carriers with Mortality Rates and Incidence of Bacteremia by Types in Selected Groups of Cases of Pneumonia

Not XXXII (not included in higher types) represent 16.7 per cent of the total number of carriers.

Unclassified organisms are not listed in the other columns.

Accepted types include I, II, III, IV, V, VII, VIII and XIV. All others are included as "higher types."

Type XXVI is included with type VI and type XXX is included with type XV.

amides, while almost all of the "state" cases occurred after 1938. The hospital cases, however, also represent a much more severe group of infections.

The incidence of positive blood cultures in the adult hospital cases of the various types is also shown in table 2. This gives one an opportunity to compare the mortality of the individual types with their "invasiveness," the incidence of bacteremia being a good index of the latter. The types seem to fall roughly into three

of these types presented positive blood cultures. The percentage of mortality in each of these types was roughly twice as high as the incidence of bacteremia. The third group includes the remaining "higher" types, which were the least invasive. With two exceptions the percentage of mortality in each of these types was from three to six times as great as the percentage of positive blood cultures.

This classification obviously cannot be considered to be a rigid one. Some of the types are obviously borderline and might be found to fall into different groups if more data were available. Furthermore the same types may behave differently under special circumstances. From the point of view of specific serum therapy of pneumonia, however, such a classification may be of help. If such serums are of value, then it is presumably in the "invasive" types that they should have their greatest use.

42 Footnotes 32, 33 and 34.

Data concerning the immune response of patients with pneumonia of the "higher" types are very scant. Two series of cases in which specific antiserums were not used⁴³ were studied at the Boston City Hospital. Homologous type specific antibodies for "higher" types were demonstrated by the agglutination test in 17 of 51 patients tested (33 per cent). By contrast, about three fourths of all pneumonias with the "accepted" types developed agglutinins.⁴⁴ Positive tests were obtained in patients with eleven of the sixteen "higher" types represented among these 51 patients; tests were done on only 6 patients of the five types (X, XIII, XV, XXI and XXII) in which totally negative results were obtained. In six other Cooper types (XXIII, XXIX, XXV, XXVII, XXVIII and XXXII) no cases were studied.^{44a} These findings may be interpreted as indicating that either (1) a large percentage of the cases of higher types are not etiologically related to the pneumonias in which they are found or (2) the "higher" types are less antigenic in addition to being less invasive, even when they are the cause of pneumonia or (3) the test used for demonstrating the antibody of these types is inadequate. Probably each of these factors is important and may be responsible, in different degrees, for the results in the various "higher" types.

Acquaintance with the relative frequency with which the various types occur in an etiologic relationship to pneumonia can serve as a diagnostic aid when one is confronted with a given case in which a pneumococcus of a given type is found only in a sputum or throat culture. Such information, however, should be used only in about the same manner as the knowledge of the relative frequency with which any given symptom, sign or laboratory finding is used in the differential diagnosis of various diseases. In the same manner it is also useful in multiple infections, either with more than one type of pneumococcus or with pneumococci and other respiratory pathogens.

In any given case of pneumonia the finding of some type of pneumococcus in cultures of the blood, lung or pleural fluid, or in cultures from some other purulent focus, may be considered as establishing the etiologic relation of that type to the pneumonia. The direct typing of sputum by the Neufeld method also permits of a relatively certain etiologic diagnosis from this source, provided (1) the sputum is obtained during the period of active infection, (2) one is reasonably certain that it was raised from the lower respiratory tract and did not come from the nasopharynx and (3) the pneumococcus of the type in question is seen either (a) as the only or predominant organism in characteristic "rusty" sputum or (b) in large numbers and as the predominant organism in purulent sputum.

44a In infants and children also homologous type specific antibodies can be demonstrated with greater regularity in pneumonias of the "accepted" types than in those associated with "higher" types of pneumococci (Finland Maxwell Shuman H I and Barnes M W. The Type Specific Agglutinin Response of Infants and Children with Pneumococcus Pneumonia. *J Immunol* to be published).

THE USE OF THERAPEUTIC ANTISERUMS IN PNEUMOCOCCIC PNEUMONIAS OF THE "HIGHER" TYPES

The early attempts to prepare therapeutic antiserums against pneumococci of the new Cooper types met with variable success.⁴⁵ There were wide variations in antibody titer, as measured by the agglutination and the mouse protection tests, both among the various types and among different horses immunized with the same type. Furthermore, the great differences in virulence of the new types of pneumococci introduced additional problems in standardization of potency. There were many other technical difficulties and costly procedures involved in the preparation of these serums which need not be detailed here. Eventually it became possible for certain laboratories to produce horse serums of reasonably uniform and high potency against a few of these types. Therapeutic trials with horse antiserums for types V and VII and then for types IV and VIII, though comparatively limited, yielded results which were sufficiently encouraging to warrant acceptance by the Council. Antipneumococcus horse serums for some of the other types were probably of equal value, but they had not been developed to the point of acceptance by the Council at the time when the use of rabbit serum was proved feasible.

In rabbits it was found possible to produce antiserums against all the specific types of pneumococci. These rabbit serums proved to be more specific and they were more uniformly of higher potency than those produced in horses and were therefore more suitable than the latter for the less frequent and so called higher types. In early therapeutic trials, severe untoward reactions were encountered which eventually became less frequent as experience was gained in processing these rabbit serums. Those now available give rise to untoward reactions of the nonspecific varieties⁴⁶ with no greater frequency and probably much less often than the antipneumococcus horse serums produced by the same manufacturers.⁴⁶ True allergic or anaphylactic reactions are distinctly less frequent with the rabbit serums.⁴⁶ Clinical trials soon indicated that, at least for the common types for which horse serums had been accepted namely types IV, V, VII and VIII, the serums prepared in rabbits merited acceptance by the Council. In addition, data were soon submitted which led the Council to accept antipneumococcus serums for types III and XIV.⁴⁷

There are a number of reasons why the establishment of the true therapeutic efficacy and usefulness of antipneumococcus serums for the "higher" types is more difficult than with the types just mentioned. 1 The multiplicity of the types, the relative infrequency with which each of them is encountered and the great expense involved in making the serums has made it difficult to keep adequate stocks of serum for all types readily available in all places where they might be immediately accessible. 2 Because the higher types are so frequently associated with atypical pneumonias and with other serious diseases and conditions ("secondary" pneumonias), they are less likely to be considered for treatment early in the course of the infection, when they might be expected to exert their maximum beneficial effects. 3 The difficulties in establishing the etiologic relation-

45 Rutstein D D Reed E A Langmuir A D and Rogers E S. Immediate Serum Reactions in Man. Classification and Analysis of Reactions to Intravenous Administration of Antipneumococcus Horse Serum in Cases of Pneumonia. *Arch Int Med* 68 25 56 (July) 1941. 46 Personal communications to the author from Dr D D Rutstein and Dr W D Sutliff.

ship of these types to the pneumonia are greater than with the "accepted" types. Because of their lower virulence and invasiveness, positive results of blood cultures or of cultures from lung or pleural fluids are less frequent, and fewer organisms are usually found in the sputum. Furthermore the "higher" types occur more often as multiple infections in cases of pneumonia and are also more frequent among the organisms which constitute the common flora of the upper respiratory tract. Even more important than any of the foregoing is the fact that chemotherapeutic agents in the form of sulfonamide compounds which are highly effective in pneumococcal pneumonias of all types became available at about the same time as the therapeutic rabbit serums for the higher types.

The use of sulfapyridine and, more recently, of sulfathiazole and sulfadiazine has spread rapidly and has essentially replaced the use of specific serums in all but a small percentage of the cases of pneumococcal pneumonia. It was natural, in view of the greater difficulties involved in the use of serums for the higher types, that proportionally even fewer of these cases would be treated with serums as compared with those of the more common of the Cooper types. By its very nature, the present chemotherapy is much less expensive than anti-serums and, as experience with it has increased, its control has required much less effort on the part of the physician and probably involved less risk to the patient. The toxic reactions which were quite significant with the use of sulfapyridine, have become less frequent and less severe with the advent of the successive compounds sulfathiazole and sulfadiazine, while the recognition and management of those reactions which occur has become a less serious problem. The wide range of effectiveness of these drugs had made possible the early initiation of treatment—a highly important factor in the success of any specific measure in pneumonia. This, in turn, has made early and rapid etiologic diagnosis less important and, for practical purposes, it has gradually been dispensed with by a large majority of physicians. Except where special interests in the problem required a continuation of the diagnostic efforts, typing has been reserved in large part for those cases in which chemotherapy is not entirely successful or for certain selected cases, usually the severest ones. This is unfortunate, since it is in just such cases that early etiologic diagnosis is most desirable.

These facts could not easily be ignored by any physician who attempted to conduct therapeutic trials with specific serums. It would, of course, be highly desirable to have a number of large and carefully controlled series of cases in which specific serum, chemotherapy and the combination of the two were applied to patients in strict rotation. The nature of these forms of treatment, however, and the numerous difficulties involved in conducting such clinical experiments have been sufficient to discourage most workers. Some early attempts to conduct such trials on a limited scale by alternating cases between serum therapy and chemotherapy indicated that specific serums in selected cases of lobar pneumonia yielded therapeutic results which, in most respects, were comparable to those obtained in corresponding cases treated with sulfapyridine.⁴⁷ Subse-

quent studies of this sort were aimed at comparing the value of chemotherapy when used alone and in combination with specific serums.⁴⁸ Attempts at strict alternation of cases on such a basis when it also permits of the immediate use of drug alone, although it may at first glance appear to be the preferable method, raises a number of problems which render the results open to considerable criticism. These problems are discussed elsewhere, together with a critical review of the results of therapeutic experiments with specific serums in general and with antipneumococcus serums in particular.⁴⁹

From a practical point of view it seems quite futile to discuss the relative merits of serum and sulfonamide compounds when used separately or in combination. There is no longer any question of adopting any one of these methods of treatment as a routine to the exclusion of the other methods, unless it be the use of chemotherapy alone. The latter is, and probably will continue to be, the treatment of first choice in all except a relatively small percentage of cases. Obviously the expense, time, effort and risks of serum therapy would then be undertaken only for possible added benefits or to avoid greater risks that might be involved in chemotherapy. The essential problems, therefore, are to determine (1) under what conditions specific serums add materially to the chances of recovery or significantly reduce the period of acute illness and (2) whether there are any conditions in which serum might advantageously be used instead of a sulfonamide compound. Answers to these problems are difficult to obtain and, in my opinion, they lie in a thorough study of a large number of consecutive individual patients⁵⁰ and will necessarily vary according to the personal experience of the investigator.

MORTALITY RATES AND THEIR INTERPRETATION

With all the foregoing factors in mind, an attempt was made to collect from various accessible sources those groups of cases in which (1) typing was carried out for all the Cooper types, (2) reasonably large numbers of cases were available and (3) the various forms of treatment under discussion were used. Since the immediate problem was the determination of the usefulness of the "higher" types of rabbit antipneumococcus serums, the data in the various therapeutic groups were essentially limited to cases treated since the summer of 1938. Contemporaneous cases treated without serums or sulfonamide compounds were available from some of the same sources, but a number of earlier cases in this category were also included in order to obtain a better approximation to the basic mortality in the pneumonias of the various types uninfluenced by either serum or chemotherapy. The cases in the various therapeutic groups are obviously not comparable. They are merely useful in determining, as nearly as possible, the mortality rates in each group under the conditions in which the therapy was employed.

The mortality rates in the collected series of cases receiving each form of treatment are shown for the

individual types in table 3⁵¹. Unfortunately, it is not possible to obtain adequate information concerning the reasons for the choice of therapy in most instances, since this factor alone may have greatly influenced the mortality rates. It is interesting to note, however, the relative proportion of cases in each therapeutic group which are of the "higher" types. Of the 9,053 cases treated with serum alone 688, or 7.6 per cent, were of the higher types, of the 12,167 cases treated with both serum and sulfonamide compounds 2,248, or 18.6 per cent, were of the higher types, among the 12,547 cases treated with chemotherapy alone 4,337, or 34.6 per cent, were of the higher types, and among the 8,101 cases in which neither serum nor drug was administered 2,812, or 28.8 per cent were of the higher types. At least one reason for the small proportion of "higher" type cases among those treated with serum is the fact that serums for these types were less readily available than those for the "accepted" types. A few relevant points concerning each of the therapeutic groups may be noted.

Cases Treated with Serum Alone—In this group the mortality in the cases of the "Council accepted" types probably corresponds to the average of the results reported prior to the advent of effective sulfonamide compounds. In a large proportion of these cases horse serums were administered, this was particularly true of the cases of types I, V and VII and somewhat less so of types II, IV and VIII. In almost all of the type III and type XIV cases, however, rabbit serums were administered. Individual reports of appreciable numbers of cases in which rabbit serums were used exclusively have shown much lower mortality figures although the cases were of average or greater than average severity.⁵² For example, Loughlin Bennett and Spitz⁵³ had only 3 deaths among 125 patients (2.3 per cent) with types V, VII and VIII pneumococcus pneumonia, of which 30 per cent gave positive blood cultures. Crisis occurred within a few hours in 82 per cent of these patients after a single dose of serum was administered. MacLeod⁵⁴ reported 4 deaths among 74 cases (5.4 per cent) other than those of type III. These results are comparable with the best results from chemotherapy in similar cases. Further-

more, these two reports include cases collected before chemotherapy was used. For the majority of the cases listed in the table, however, it must be borne in mind that, since effective chemotherapy was available, probably drugs in addition were employed in some of the severer cases and these are therefore taken out of this group.

The serum treated cases of the higher types fall into four groups. The first includes cases of types XII, XX, XXV and XXVII in which the mortality was lower than in the corresponding cases in the other therapeutic groups. The second group includes cases of types IX, X, XVII, XVIII, XXIV and XXXIII. In each of these types the mortality was less than 15 per cent and was comparable, in general, with the results in serum treated cases of the "accepted" types. The relative mortalities in this group, when compared with the corresponding mortality rates in the other therapeutic groups, were also similar to those of the "accepted" types. In these two groups of types it is fair to assume that serum exerted a definite beneficial effect on the mortality rates. In some of these types, and in others of the serum treated cases, the numbers of cases are small and the significance of the fatality rates may therefore be open to question.

The third group includes types VI, XIX, XXII, XXIII, XXIX and XXXII, in which the mortality was higher in the serum treated cases than in the other two therapeutic groups but was lower than in the cases of the corresponding types in which neither serum nor sulfonamide derivatives were used. In this group possibly some benefit resulted from the serum treatment although this cannot be determined without further data bearing on the choice of cases. In the last group, which includes types XI, XIII, XV, XVI, XXI, XXVIII and XXXI, no possible benefit could be ascribed to the serum at least on the basis of the mortality rates. The latter were higher than in the cases of the corresponding types treated with sulfonamide compounds alone or with serum or in those in which neither therapy was used. The number of cases of some of these types, however, was quite small.

The mortality in the whole number of cases of the higher types that were treated with serum alone was greater than that of the "accepted" types. The mortality in the former was about two thirds and in the latter less than one half of that of the corresponding types among the cases in which neither serum nor sulfonamide compounds were employed.

Among all the serum treated cases one must reckon with the possibility that many of them were included for this treatment alone because of complications which precluded the use of sulfonamide compounds. The prognosis for recovery from pneumonia in some cases of this sort is very poor as, for example, in those with severe renal or hepatic disease or after extensive abdominal operations.

An appreciable number of the earlier cases included among those in which serum alone was used were treated before the advent of sulfapyridine or they were collected in the course of studies which precluded the use of drugs. Furthermore, a number of these cases were treated during the developmental stage of rabbit serum therapy and lots of serum for clinical trial were employed before they were released for general use. Some of these lots were of relatively low potency and gave severe untoward reactions.

The problem of subtypes that has been discussed must be considered especially in relation to the results

51 The data in this table were derived from the following sources: Boston City Hospital (Finland Spring and Lowell²⁴ and Finland Lowell and Strauss²⁵); Harlem Hospital (data furnished by Dr. Bullowa) and the health departments of New York State²⁶, Illinois²⁷ and Pennsylvania²⁸. obtained in types IX, X, XI, XV, XVI and XVIII. Some, at least, of the poor results obtained in cases of these types were very probably attributable to this cause.⁵⁵ In the preparation of most of the recent lots of serums, cognizance is taken of the subtypes, and antibodies for some of them are included in the therapeutic serums.

In the evaluation of specific curative agents in the treatment of pneumococcal pneumonias, the effect on the clinical course may be considered of almost equal importance with the reduction in the mortality rates. This is particularly true when only small numbers of cases are available. Almost every one of the writers

then serum was used after a varying interval because either (1) the response to the drug did not seem adequate, (2) the drug produced toxic effects which interfered with the continuation of adequate treatment or (3) new data indicating a poor prognosis (positive blood culture, evidence of a spreading pneumonic lesion and so on) became available before adequate improvement had taken place from the drug. A small number of these patients received serum first and then were given chemotherapy because of an inadequate response to the serum or because of the finding of a mixed infection or of some other complication. It is to be expected, therefore, that these cases should include the

Type XXVI is included with type VI and type XXX is included with type XV.

Type XXXIII is listed because therapeutic serum was available for most of the period covered.

The large majority of patients were adults. The state cases include infants and children. The latter are estimated to constitute less than 5 per cent of the patients treated with serum either alone or with chemotherapy, about 15 per cent of those treated with sulfonamide compounds alone and about 10 per cent of those receiving no specific treatment.

Horse serums were used in a considerable proportion of the patients with types I, II, V and VII and in a small number of those with IV and VIII. Rabbit serums were used in almost all the remaining cases.

The sulfonamide compounds used include chiefly sulfapyridine, sulfathiazole and sulfadiazine or their sodium salts.

who has reported on the serum treatment of any appreciable number of cases has emphasized the fact that recovery by crisis following homologous type specific serum treatment of the higher type cases is usually as rapid and as dramatic as in the cases of the more common or "accepted" types.

Cases Treated with Serum and Sulfonamide Compounds.—In evaluating the mortality in these cases it is important to bear in mind that only a small proportion of them received the combined treatment from the start. Furthermore, most of those in whom the two kinds of treatment were begun at the same time or within a short time of each other probably represent the poorest risks. For the most part, this group includes patients to whom chemotherapy was given first and

highest percentage of cases of the worst prognostic groups, namely those in the oldest age groups, those with positive blood cultures or multiple lobe involvement⁵⁶ and also many "secondary" and atypical pneumonias.⁵⁷

For the most part, the mortality for each type in the cases treated with serum and sulfonamide compounds is quite comparable to that found in the corresponding cases treated with serum alone, considering the small numbers of cases among the latter. Here also the mortality was greater in cases of the "higher" types than in those of the "Council accepted" types. The gross mortality in each of these two groups was slightly lower than in the corresponding cases treated

⁵⁶ Rosi, Sagen and Prange.⁵⁰ Finland. Spring and Lowell.⁵¹ Finland. Lowell and Strauss.⁵²

⁵⁷ Finland. Spring and Lowell.⁵⁴ Finland. Lowell and Strauss.⁵⁵

⁵⁵ Davidson and Bullowa.⁷ Carey.⁴⁸

with serum alone. This differs from some of the results previously reported from large hospitals, in which the mortality was appreciably higher in the cases in which combined therapy was given. Much of the difference, as will appear later, is due to the inclusion of cases treated in statewide programs in which the greater use of serums was facilitated and probably encouraged.

An evaluation of the relative effect of the combined treatment as compared with chemotherapy alone is obviously not possible from these data. Much depends on the relative numbers of cases in each of the prognostic groups.⁵⁰

In the cases in which combined therapy was used, as in those in which serum alone was employed, the mortality rates in the cases of the various higher types were, generally speaking, similar to those obtained in the cases of the "Council accepted" types. This is of particular significance since it must be assumed in view of what has already been said about the use of higher type serums, that more stringent indications were probably required by most physicians before undertaking to use them.

From the point of view of the clinical response, the experiences at the Boston City Hospital and those of many other observers have indicated that an appreciable proportion of the cases showed a direct response by crisis following serum, even after they had failed to improve under chemotherapy.⁵¹ Many of the cases, however, show only moderate additional improvement immediately, and this is particularly true in the cases in which purulent complications, mixed infections or extensive pulmonary lesions were present.

TABLE 4—Outcome of Cases of *Pneumococcus Pneumonia* Treated with *Antipneumococcus Serum* and *Sulfonamide Compounds*

(Reported to the New York City Department of Health from Oct. 1, 1940 to Sept. 30, 1941)*

Evaluation of Result	Cases of Accepted Types	Cases of Higher Types
Recovered cases (total)	110	114
1 Temperature normal 48 hours after therapy and thereafter	80	13
2 Striking effect on temperature in 48 hours but specified incomplete or time or completeness not specified	90	26
3 Striking effect after serum not after chemotherapy	37	11
4 Striking effect after chemotherapy not after serum	0	0
5 Lack of effect demonstrated (adequate treatment for 3 days)	10	2
6 Recovery not 1 2 3 4 or 5 or not described	293	67
Deaths (total)	176	56
1 Less than 24 hours after therapy	15	7
2 More than 24 hours after therapy	111	49
Grand totals	606	170

* Data supplied by Dr. W. D. Sutcliffe, assistant director (pneumonia), Bureau of Laboratories.

Thus, it is seen in table 4 that, in most of the cases treated in New York City with both serum and drugs and in which data are available, specific serums probably contributed to the recovery. The proportion of cases of the "higher" types that probably benefited from serum was essentially the same as in those of the "accepted" types. An evaluation of the effect of serum in the "higher" type cases treated at the Boston City Hospital is shown in table 5. In the recovered cases,

serum was considered to have a definite beneficial effect in most instances.

Cases Treated with Sulfonamide Compounds but Without Serum—The mortality in these cases was lower than for each of the other therapeutic groups.

TABLE 5—Evaluation of the Clinical Effect of Specific Antiserum in Patients with "Higher Type" *Pneumococcus Pneumonia* or *Meningitis*

Boston City Hospital, 1933-1941

Evaluation of Result	Pneumonias		Meningitis
	Serum Alone	Serum and Sulfonamide Compound	Serum and Drug
Recovered cases (total)	23	20	79
1 Severe cases, excellent or good response attributable to serum	17	11	19
2 Good or fair response, role of serum indeterminate	2	9	1
3 No obvious effect from serum	-	0	0
Total cases (total)	6	12	19
1 Treatment with serum begun while patient was moribund	-	5	5
2 Adequate trial but no apparent benefit from serum	0	2	3
3 Temporary improvement attributable to serum (including cases with endocarditis or death due to other causes)	1	5	11
Grand total	24	22	62

A few of the cases were obtained from reports made to the Anti-toxin and Vaccine Laboratory of the Massachusetts Department of Health and were furnished by Dr. C. C. F. Ed. all acting director.

and this was true for almost all types. Most of these cases are from sources where serums were also used to a greater or lesser extent. It must be assumed, therefore, that the lower mortality is attributable, at least in part, to the use of serum in some of the severe cases. This inevitably excludes an appreciable proportion of cases from the "drug alone" group and includes them under the combined therapy. As a result the case fatality rates in the latter are increased, and those in the former are decreased proportionally.

It is of interest that the mortality in the various higher types was, for the most part, appreciably higher than in the "accepted" types. The mortality in all the latter cases, after excluding those of type III, was 5.6 per cent. A lower mortality was noted in only 4 of the higher types (VI, XXI, XXIV and XXVII). From what has been said previously, this is probably the result of the inclusion of a greater proportion of atypical and "secondary" pneumonias among the cases of the higher types that were treated only with drugs.

Cases in Which No Serum and No Sulfonamide Compounds Were Administered—Over two thirds of all these cases occurred before rabbit serums or effective sulfonamide compounds became available. The mortality rates, at least in the cases of the higher types, therefore represent a fair approximation of the basic mortality in cases of these types uninfluenced by serums or chemotherapy. The mortality rates in the higher types in this group were generally lower than in "Council accepted" types.

THE CHOICE OF CASES FOR THE VARIOUS FORMS OF THERAPY AND ITS EFFECT ON MORTALITY

It is obvious from what has been said that the proportions of cases of the various prognostic groups that are chosen for each kind of therapy will, in a large measure, determine the case fatality rate in all the

cases in which that kind of therapy is employed. This does not take into account the reasons for choosing some particular therapy in the individual cases, and these may be of similar importance. When multiple therapy is used, the estimation of the various prognostic factors alone, for instance, by "adjusted fatality rates,"⁵⁰ though indicating the greater severity of the cases chosen, does not fully reflect the additional value of the second therapy used.⁵¹ In the cases from Illinois³⁰ it was shown that the cases in which combined therapy was used included a larger proportion of those in the worst prognostic groups. This was also true at the Boston City Hospital²⁷ and probably wherever the combined treatment has been used. In table 6 are shown the case fatality rates from various kinds of treatment in the cases from Illinois and from two large hospitals. The latter were chosen because they represent cases that were studied in a more uniform manner and also because the results of blood cultures were available in almost all of the cases. The effect

serum nor sulfonamide derivatives were used. Serum alone was also used in an appreciably higher proportion of the hospital cases. The more frequent selection of cases for combined treatment in the Illinois series probably explains, in part at least, the lower mortality in this group of cases as compared with the cases in which serum alone was used, whereas in the hospital group the more rigid selection of cases for combined treatment resulted in a relatively higher fatality rate with this therapy.

In both series, relatively more cases of the "accepted" types than of the higher types were treated with serum, either alone or with drugs. The reverse was true for the cases treated with drug alone, as might be expected. This form of treatment was used in a greater proportion of the higher type cases. The fatality rates in all the cases of the higher types were slightly higher than those of the accepted types in the corresponding therapeutic groups of both series, except for the group with no serum or drug in the Illinois series.

TABLE 6—Mortality and Distribution of Cases of "Accepted and of Higher" Types of Pneumococcal Pneumonia According to the Kind of Treatment Used in Two Selected Series

		Boston City Hospital 1933-1940 and Harlem Hospital 1938-1941												
Pneumococcus Types	Specific Therapy	Number of Cases	Per Cent of Cases	Died	Per Cent Died	Per Cent with Positive Blood Cultures	Cases with Positive Blood Cultures			Illinois 1938-1941				
							No of Cases	Per Cent of Cases	Died	Per Cent Died	No of Cases	Per Cent of Cases	Died	Per Cent Died
Council accepted types	Serum	330	19.9	63	11.8	21.0	117	21.4	42	35.9	848	9.8	102	12.0
	Serum and sulfonamide compounds	610	27.7	97	15.9	32.1	193	30.2	69	35.8	4,814	55.3	490	10.2
	Sulfonamide compounds	1,118	41.6	144	12.9	17.9	200	36.5	64	32.0	2,768	31.8	132	4.8
	No serum no sulfonamide compounds	470	15.8	113	24.0	8.9	38	6.9	36	94.7	271	3.1	59	21.8
	Total	2,658	100.0	417	15.5	20.4	548	100.0	211	38.5	8,701	100.0	783	9.0
"Higher" types	Serum	118	0.3	10	13.6	10.2	12	13.6	2	16.7	172	4.1	41	23.8
	Serum and sulfonamide compounds	82	6.5	20	31.7	22.0	18	20.5	9	50.0	1,631	36.0	200	13.1
	Sulfonamide compounds	460	36.6	98	21.1	6.0	30	34.1	9	30.0	2,153	51.5	111	5.2
	No serum no sulfonamide compounds	600	47.6	176	29.1	4.0	28	31.8	27	96.4	396	7.8	42	12.9
	Total	1,270	100.0	316	24.1	6.0	88	100.0	47	52.4	4,152	100.0	394	9.4
All types	Serum	603	16.5	79	12.1	19.8	129	20.3	44	34.1	1,020	7.9	143	14.0
	Serum and sulfonamide compounds	692	17.5	123	17.7	30.5	211	33.2	78	37.0	9,345	49.2	690	10.9
	Sulfonamide compounds	1,583	40.0	242	15.3	14.5	230	36.1	73	31.7	4,921	38.2	243	4.9
	No serum no sulfonamide compounds	1,030	26.0	269	28.1	6.4	66	10.4	63	95.5	597	4.7	101	10.9
	Total	3,908	100.0	733	18.5	10.3	636	100.0	258	40.6	12,883	100.0	1,177	9.2

The term sulfonamide compounds here refers to sulfapyridine, sulfathiazole or sulfadiazine.

of this factor alone on the choice of therapy and on the resulting fatality rates can thus be estimated. Cases of the "higher" and of the "accepted" types are also compared.

The outstanding differences in the choice of cases in these two series is the higher proportion of cases from Illinois in which the combined treatment was used and the higher proportion of hospital cases in which neither

59 For example let us assume that the expected case fatality rate in cases of type I pneumonia in the fifth decade of life with bacteremia and a single lobe involved is 50 per cent. If we then begin with 100 such patients and give them all chemotherapy, it is fair to assume that the great majority of the 50 patients who would eventually have recovered without specific therapy would respond fairly promptly to chemotherapy alone. If we assume that 40 patients responded in this manner to a sulfonamide derivative there would remain 60 possible candidates for additional serum therapy after eighteen to thirty-six hours. If 50 of these 60 patients were then chosen at random and treated with serum the highest expected death rate in the 50 cases ending up with drug alone is 20 per cent and the lowest expected fatality rate in the 50 cases ending up with both treatments is 80 per cent and the highest possible is 100 per cent. If the actual death rate was 10 per cent in the drug alone group and 20 per cent in the combined therapy group the maximum reduction in death rate ascribable to the drug in the former is from 20 per cent to 10 per cent and the reduction in the latter that could be ascribed to drug would be from between 80 and 100 to between 40 and 50 per cent. The additional drop to 20 per cent would then be ascribable to serum. The low fatality rate in the drug alone group therefore is due as much to preselection among the cases with various prognostic factors as it is to the incidence of these factors. Solely on the basis of the incidence of the prognostic factors chemotherapy alone would here be considered to be twice as effective as the combined treatment in reducing the case fatality rate.

In the hospital series the high fatality rates in the cases with combined therapy are associated with a correspondingly high incidence of positive blood cultures. This was true both in the cases of the "accepted" types and in those of the higher types. The mortality in all the "treated" bacteremic cases was quite similar regardless of whether serum, drug or both were used. The apparent differences noted under the various forms of therapy in the cases of higher types may be due to the small numbers of cases involved. Among the bacteremic cases, the proportion of those chosen for combined therapy (33.2 per cent) was almost twice as great as in the entire group (17.5 per cent), and for the cases of the higher types it was three times as great (20.5 and 6.5 per cent respectively). The incidence of positive blood cultures in the treated cases was highest in those receiving combined treatment and lowest in those treated only with drugs. Bacteremia, as expected, was more frequent in the cases of "accepted" types than in those of the "higher" types.

Results in Infants and Children—Data for evaluating the effects of specific serums in infants and children are very scant. The various "state" series include considerable numbers of cases in the lower age groups,

but those receiving serum are very few. The added difficulties of "typing," the frequency with which multiple types are encountered, the low basic mortality in children over 2 years of age and the even lower mortality rates in infants and children treated with sulfonamide compounds alone—all these factors have left but little in the way of inducements for the use of serums except in rare cases. There is therefore little information of significance concerning the use of serums of the higher types in such cases.

Carey and Cooley⁶⁰ used antipneumococcus rabbit serums in 106 cases, including those of types I, V, VII, VIII, XIV, XV, XVI, XVIII, XIX and XXIII, and found them equally effective in all these types except in 2 cases of type XVIII, which were probably subtypes or other related types. They also used sulfapyridine in 246 cases and found this drug effective in all thirty-two types. In a subsequent paper Carey⁴⁸ reported that antipneumococcus rabbit serums, combined with sulfapyridine or sulfathiazole, seem to possess a slight advantage over the use of these drugs alone. The duration of the acute disease after treatment was started was less than with chemotherapy alone, and recurrent pneumonia was not observed in the cases in which the combined treatment was used but was frequent after the drugs were used alone. In view of all the various factors involved, however, he felt that the routine administration of serum in infants and children was not practical except in the event of pneumococcal bacteremia, widespread involvement of the lungs or severe toxicity from the infection.

USE OF SERUMS IN PNEUMOCOCCIC MENINGITIS AND PERITONITIS

The use of serums in pneumococcal meningitis and peritonitis, as it concerns meningitis, has been reviewed recently and little need be said here.⁶¹ There can be no question that almost all of the recent recoveries in this disease are ascribable directly to the use of sulfanilamide and other sulfonamide compounds in the sense that these recoveries probably would not have occurred without the use of such drugs. In a large number of the reported cases of recovery, however, specific serum was used in addition. We are therefore confronted with the same problem as in the cases of pneumonia. In many of the cases the serum was given after an appreciable interval, during which evidence of cure with the drugs alone was not forthcoming. The finding of a similar mortality in a collected series of cases treated with drug alone and in similar cases in which serum in addition was used³⁷ can be interpreted only as indicating that the drugs alone are capable of bringing about recoveries, but it does not indicate the value, if any, of the serum added in those cases in which it was used. It cannot be said that the serum was of no value unless treatment with both the serum and the drug was begun together in all cases. On the other hand, it is more reasonable to suppose that the additional administration of serum helped to salvage a large proportion of the patients who were doing poorly under chemotherapy. A careful study of individual cases⁶² has yielded more direct evidence of

additional benefit from serum in the rapid sterilization of the cerebrospinal fluid in certain cases after chemotherapy alone had failed to bring about this result even when used intensively for a reasonable period. The high proportion of cases of pneumococcal meningitis which are of the higher types (table 1) indicates that serums for these types should find a place in the therapy of these cases.

Data on the use of serum in pneumococcal peritonitis are very scant.⁶³ Sulfanilamide and other sulfonamide compounds have proved effective when used alone in some of these cases, and antipneumococcus serums have been used in addition in others in which recovery occurred. The additional value of specific antiserums, while fairly well established in experimental infections in animals, is even more difficult to determine in human cases of pneumococcal peritonitis than it is in pneumonia or meningitis. The combined treatment is probably indicated, as in the latter infections, but the mortality is still high in spite of the use of both serum and drugs.

COMMENT

The two main questions that arise with respect to the antipneumococcus serums of the higher types may be stated thus: 1. Are they effective in the treatment of cases of pneumonia in which these types occur? 2. Are they useful in the treatment of pneumonia or of other pneumococcal infections now that effective sulfonamide compounds are available for the treatment of the same conditions? With respect to the second there are really two questions involved: (a) Are there any conditions in which the serum might be used alone without drugs? (b) Are the serums of value as a supplement to the sulfonamide compounds?

The answer to the first question is far as it concerns the great majority of the higher types, can, with reasonable assurance, be stated in the affirmative. It must, of course, be added that the effectiveness of the serums of the higher types depends on the same principles which govern the effective use of serums of the "accepted" types. They must be used in the homologous type infection and in adequate amounts. They are also most effective when given early in the course of the disease.

As far as the practical usefulness of these higher type serums is concerned, that may depend on the circumstances under which they are used. They may, of course, be of value when used alone in cases in which sulfonamide drugs cannot be tolerated. They may be resorted to in cases in which the organism is resistant to the action of these drugs or when, for this or for other reasons, there is a poor response to chemotherapy. In certain cases of great severity, as when there is bacteremia or an extending pulmonary lesion or the early development of purulent complications, these serums, when used in addition to the drug, may be of great benefit. When used in such cases, either from the start or after comparatively brief intervals of chemotherapy alone, they may play an important part in the eventual recovery or in curtailing the period of the acute illness.⁶⁴

The fact that the mortality in cases of pneumonia of the higher types is still comparatively high with the use of chemotherapy alone may be a reflection of the severity of the host factors involved in these cases. It may also be interpreted as indicating that the part played by the pneumococcal infection is not entirely overcome by the drugs alone and, at least in some of these cases, serum may have a significant part to play. The proportion of cases of the higher types in which serums may be useful is difficult to evaluate, but it is probably quite small.

These statements hold true for cases of pneumonia, in which there are often difficulties in establishing the etiologic relationship of the higher type pneumococcus to the disease. In cases of pneumococcal meningitis or peritonitis, on the other hand, the etiologic significance of the organism found is not in doubt. The proper use of specific serums in such cases may be considered of great value and should be encouraged. Since in appreciable proportion of such cases, at least those of meningitis, are caused by pneumococci of the higher types it would seem highly desirable that potent serums for these types be available.

SUMMARY AND CONCLUSIONS

Many new types of pneumococci have been added to the original types I, II and III and the Cooper types IV to XXXII. A few of the newer types have been found to be of significance in disease, but many of these have been shown to be closely related to the previously classified types. With respect to diagnosis and treatment however, the difficulties introduced by these types can be and, in part, have been minimized by the preparation of both diagnostic and therapeutic serums which cover the groups of related types.

All of the types I to XXXII and most of the newer ones have been found to be etiologically related to pneumonia and other infections, and they have all been found in healthy carriers who have had no known contact with such infections. The relative frequency with which each of the various types is found to be pathogenic varies considerably. The "higher" types on the whole, have been found to be less invasive than the "Council accepted" types (I, II, III, IV, V, VII, VIII and XIV). This varies considerably for the individual higher types, however, and a few of them have proved to be as invasive as some of the Council accepted types.

The mortality in the pneumonias associated with each of the higher types does not bear any apparent relation to its invasiveness, as indicated by the frequency with which it is found in positive blood cultures. The high mortality in cases of pneumonia of the higher types is considered to be the result of the host factors, as indicated by the frequent occurrence of these types in secondary and in atypical pneumonias.

Case fatality rates have been computed for more than 40,000 cases of "typed" pneumococcal pneumonia, in relation to the kind of specific therapy employed. These cases were collected from many sources, including chiefly large hospitals and the pneumonia bureaus of several states. The case fatality rates were computed for each of the pneumococcus types in cases treated with specific serums or sulfonamide compounds, used alone or in combination, and also in a group of cases in which neither of these agents was used.

These data indicate that both serums and sulfonamide compounds are effective. For many of the higher types the specific serums, used alone or in combination with the drugs, were, relatively speaking, as effective as

in the accepted types. Clinical results, as indicated by careful observations in successive individual cases, confirm this impression.

Cases of pneumococcal meningitis are frequently caused by strains of the "higher" types. Serum alone is probably of little or no value in treatment of pneumococcal meningitis, regardless of the type of the organism. The reported results in collected series of cases of meningitis indicate that the mortality is the same in cases treated with sulfonamide drugs alone and in those in which antipneumococcus serums are used in addition, as in cases of pneumonia. Such a result indicates merely that the sulfonamide compounds are effective in these conditions. There is good reason for believing that serum was of added benefit in these cases and was probably responsible for many of the recoveries in the cases in which it was used.

It is concluded that antipneumococcus serums of the higher types are effective and that they have a limited field of usefulness in the treatment of cases of pneumococcal pneumonia and meningitis of these types.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Secretary

DEHYDROCHOLIC ACID (See New and Nonofficial Remedies, 1942, p. 299)

The following dosage form has been accepted:

THE LAKESIDE LABORATORIES, INC., MILWAUKEE

Tablets Dehydrocholic Acid 0.25 Gm (3/4 grains)

SODIUM DEHYDROCHOLATE (See New and Nonofficial Remedies, 1942, p. 301)

The following dosage forms have been accepted:

THE LAKESIDE LABORATORIES, INC., MILWAUKEE

Ampules Solution of Sodium Dehydrocholate 20% W/V 10 cc

Ampules Solution of Sodium Dehydrocholate 20% W/V 30 cc vial Preserved with 0.5 per cent chlorobutanol

DIETHYLSTILBESTROL (See THE JOURNAL, June 20, 1942, p. 635)

The following dosage forms have been accepted:

ENDO PRODUCTS, INC., RICHMOND HILL, N. Y.

Ampules Diethylstilbestrol, 0.5 mg per cc 1 cc in sesame oil

Ampules Diethylstilbestrol, 1.0 mg per cc 1 cc in sesame oil

Ampules Diethylstilbestrol, 2.0 mg per cc 1 cc in sesame oil

Ampules Diethylstilbestrol, 5.0 mg per cc 1 cc in sesame oil

THE LAKESIDE LABORATORIES, INC., MILWAUKEE

Ampules Diethylstilbestrol in Oil, 0.25 mg per cc 1 cc in sesame oil containing 0.5 per cent chlorobutanol

Ampules Diethylstilbestrol in Oil, 1.0 mg per cc 1 cc in sesame oil containing 0.5 per cent chlorobutanol

Ampules Diethylstilbestrol in Oil, 2.0 mg per cc 1 cc in sesame oil containing 0.5 per cent chlorobutanol

Ampules Diethylstilbestrol in Oil, 5.0 mg per cc 1 cc in sesame oil containing 0.5 per cent chlorobutanol

Tablets Diethylstilbestrol 0.25 mg, 0.5 mg, 1.0 mg, 2.0 mg and 5.0 mg

NICOTINIC ACID (See New and Nonofficial Remedies, 1942, p. 561)

The following dosage form has been accepted:

PARKE, DAVIS & COMPANY, DETROIT

Tablets Nicotinic Acid 50 mg and 100 mg

PROBLEMS OF MEDICAL MANPOWER

If there is any one phase of the manpower problem that has been handled from the first with something resembling scientific procedure, it is the utilization of the medical profession. We have always had a reasonably exact inventory of our medical assets. That inventory was made exact before Pearl Harbor. By the President's order a scientifically minded agency was established to distribute these assets properly among Army, Navy, industry and the civilian population. They recognized the need of the armed forces for a definite number of young, well qualified men. They recognized the desirability that industry be supplied with physicians trained in industrial medicine. They realized, indeed, that an expanded, speeded up industry would require more men than were available and secured the cooperation of all volunteer medical agencies in attaining that objective by training additional men. They established a quota for the present of one physician to fifteen hundred civilian population, although we could go on to one to three thousand in many areas without touching prewar levels in those areas. They have realized the need for meeting new demands such as those that prevail in new industrial and munitions areas. For example, only as recently as December 6 the Federation of State Medical Boards of the United States recommended that temporary licenses be provided for the duration of the emergency so that qualified physicians licensed outside the states which now require additional personnel may be brought in to serve the new centers of population. Relocation of physicians to meet new needs is already under way, it should soon be wholly efficient.

The directing board of the Procurement and Assignment Service is doing its utmost to assure the main-

tenance of a continuing supply of physicians of a standard equal to that supplied in the past—and that has been the highest of any nation in the world. More than twenty-eight thousand physicians volunteered and gave their services without fee of any kind to the Selective Service Boards. More than forty thousand physicians gave up their careers in civilian medical practice to serve with the armed forces. The directing board of the Procurement and Assignment Service for Physicians, its corps area representatives, its consultant committees, its state and county representatives, some hundreds in all, serve without one cent of remuneration. The hundreds of physicians on the consultant committees of the Division of Medical Sciences of the National Research Council and on the Office of Scientific Research and Development serve day after day at considerable sacrifice of time and income without one cent of remuneration. Throughout the nation thousands of doctors give of their time and effort in the agencies devoted to civilian defense, certifying the young and the old and the sick and disabled for extra fuel, gasoline and rationing of foods, and this service too without remuneration. Can any other profession or trade match this remarkable record of self sacrifice?

Yet they have not had even the appreciation that is their due. Just recently the *Saturday Evening Post* carried a half baked, incompetent, incomplete article on the shortage of doctors, apparently exalting the manner in which Great Britain has handled the problem. Neither the British nor the American situations are presented adequately. The press has carried the news of the attempts that have been made to toss the utilization of American medicine for the emergency into the arena of political football. Striving for political advantages, assaults have been made publicly on the motives, even the integrity, of the Procurement and Assignment Service and of the physicians who participate in its efforts. Fortunately for the American people, those efforts seem now to have failed. Serene in the confidence of the humanitarian, idealistic unselfishness of their work, they go forward even now planning scientifically to maintain for the armed forces and the people of America during 1943 and even during 1944 and 1945, if that should be necessary, a maximum personnel of high quality in the field of medicine, assuring to the people the best that medical science has achieved to keep them free from the fears of sickness, pain, disease and death.

IMMUNITY AND PROTEIN RESERVES

According to a recent presidential address before the American Association of Immunologists by Dr Paul R Cannon¹ the last two decades have seen the general acceptance of a new theory of specific antibody production with numerous practical applications to nutritional physiology in wartime.

Toward the close of the nineteenth century the accepted theory of specific immunity was based on Ehrlich's specific receptor hypothesis. This assumes that specific antibodies preexist as hereditary "receptors" or "side chains" in fixed tissue cells from which they are given off as a result of contact with corresponding specific antigens. Accumulated clinical and experimental evidence eventually led to an almost unanimous discarding of this theory in favor of the concept that protective antibodies are newly formed chemical complexes synthesized as a result of the action of normal intracellular enzymes.² Antibodies were conceived to be acquired chemical characters, whose method of synthesis became a feasible problem in biochemical research.

Numerous biochemists became interested in this basic problem. Breml and Haurowitz³ of Czechoslovakia, for example, studied *in vitro* reactions between purified alien hemoglobin and rabbit precipitin. Analyses of the resulting precipitates by colorimetric, chemical and enzymic methods brought the conclusion that the precipitating antibody is chemically identical with normal rabbit serum globulin except for the spatial arrangement of its constituent amino acids. From this it seemed evident that specific precipitins are normal serum globulins whose intracellular synthesis is modified by the "templating" action of the absorbed antigen. The locally synthesized "antigenic template" thus replaced the hereditary "cell receptor" of the earlier theory.

In his presidential address Cannon reviewed the accumulated experimental evidence in support of the "template" theory, with additional evidence suggesting that the "antigenic template" is synthesized from the intracellular protein reserves. Luck⁴ and others showed that a high protein diet leads to an increase in fixed tissue protein reserves with parallel increases in circulating serum globulin. A diminution in cytoplasm protein associated with decreased serum globulin as a result of low protein diets was demonstrated by Elman and Heifetz.⁵ These facts suggest the probable importance of a luxury protein diet for the maintenance of adequate "antibody matrix" (protein reserves) to serve as basic materials for specific antibody templation.

If so the immunologic potential of the reticuloendothelial system, for example, would vary quantitatively with the amount of locally available protein reserve.

This suggested relationship is in line with statistical evidence covering the increased susceptibility to infectious diseases observed as a result of dietary insufficiency during the first world war. Cannon was able to confirm this relationship on experimental animals. Rabbits whose protein reserves had been reduced by low protein diets showed a distinctly subnormal capacity to produce specific antibodies.

The accumulated evidence in support of the relationship between protein reserves and specific immunity is of particular interest at present in view of the popular overemphasis of the role of vitamins in promoting antimicrobial resistance. There is a resulting popular underestimate of the basic importance of a luxury protein intake. Without more than enough protein to maintain nitrogenous equilibrium, antimicrobial vitamins are immunologically ineffective. In the words of Madden and Whipple,⁶ "The reserve store (of protein) is the bulwark against infection."

SEASICKNESS AND AIRSICKNESS

About 40 per cent of any population group, Schwab¹ points out, are susceptible to seasickness on sudden exposure to rough weather at sea. About 5 per cent of such a group are subject to intractable seasickness. Rough estimates are that between 0.25 and 0.5 per cent of sea going people are afflicted with chronic seasickness. During wartime conditions when complete cooperation of all sea going personnel is often required, the percentage and seriousness of seasickness may affect the efficiency of handling both merchant and combat vessels. Schwab says that chronic seasickness in naval personnel may be divided into two groups: those who are constitutionally sick with a history of car, bus and other sickness, whose efficiency at sea is extremely low, and those who have severe seasickness without the history of other sicknesses on shore and with a fair degree of efficiency at sea. He suggests that those in the first group are not useful afloat and might be either discharged from the Navy or placed on shore duty. Those in the second group tend to improve with time or treatment or with transfer to larger ships. Gastrointestinal abnormalities were found in over half of the whole group. Schwab did not find correlation with background, race or body type in either of these forms of seasickness. Persons falling in the first group may be readily identified, he claims, by the use of a simple questionnaire.

A related problem of possibly even greater urgency is airsickness. Airsickness is a syndrome which

includes sweating, pallor, nausea and vomiting. These symptoms occur primarily while the person is in the air, but cases have developed after the flight has been completed. Flaherty reports that airsickness is frequently found among student pilots and usually occurs during the phase of training in acrobatics. If not properly treated, airsickness may be the cause of failure in making satisfactory progress in flight training. There is, he says, a close neurologic relationship between the vestibular apparatus and the eye. Aisickness is due to poor orientation in space. It can ordinarily be overcome when a student becomes oriented in the air by using his eyes to pick up points of reference on the ground.

Flaherty proposes a program to aid in ocular orientation. The program includes adjustment of the seat, tightening the safety belt, keeping the eyes out of the cockpit and on a distant object, and avoidance of repetition of a maneuver. During a ten months period he treated an average of eighteen students a month for airsickness by this means with satisfactory results. Five students were dropped from flight training because of airsickness, only one of whom was treated according to the advised method. This one had a record of previous car sickness, train sickness and swing sickness and his training was discontinued prior to the acrobatic stage.

CONSTITUTIONAL EFFECTS OF DYSENTERY TOXIN

A long discarded clinical theory is revived as a result of studies of the systemic action of dysentery toxin recently reported by Penner and Bernheim¹ of Mount Sinai Hospital, New York. A century ago Sydenham², Comodi³ and others assumed that dysentery is a constitutional disease of which the colonic manifestations are but relatively unimportant secondary features. With the introduction of modern bacteriologic methods, however, dysentery came to be viewed as a strictly local disease due to the direct action of the dysentery bacillus on the intestinal wall. The constitutional symptoms of the disease were ignored except as possible consequences of the local microbic lesion. Doubt as to the validity of this interpretation was expressed by pathologists, who called attention to the clinical evidence that a period of toxemia precedes the onset of the intestinal symptoms by several days and frequently persists for some time after.

From the point of view of the pathologic anatomists, bacillary dysentery is a diphtheritic, ulcerative process similar to the lesions that may occur as a result of

homeostatic responses to various shocklike conditions. In studying necropsy material from 47 cases of toxic or postoperative ulcerative and diphtheritic enteritis, Penner and his colleagues were impressed with the association of all their cases with shocklike conditions and with the fact that all of the earliest anatomic changes were in the submucosa. They traced the successive vascular events leading to the ultimate necrosis of the epithelium and concluded that the vasomotor mechanisms which occur in shock are responsible for the terminal lesion.⁴ This conclusion was confirmed by the production of a similar chain of vascular events leading to digestive tract ulceration in laboratory animals by repeated daily intraperitoneal injections of epinephrine.

To test the possibility of a similar vasoconstriction, production of the colonic lesions of bacillary dysentery, Shiga toxin was prepared by the "slow method" of Ohtsky and Kligler.⁵ The potency of this toxin was such that 0.25 cc. per kilogram injected intravenously killed rabbits within forty-eight hours. In the initial experiments this toxin was injected intravenously in doses of 0.5 cc. per kilogram into dogs, control injections being made with sterile broth or with heat inactivated Shiga toxin. The toxin injection was followed by shocklike symptoms which persisted for about eighteen hours and were followed by a gradual return to normal. Blood examinations made at fifteen to thirty minute intervals during this shock showed a significant rise in hemoglobin, erythrocyte count, hematocrit reading and specific gravity of the whole blood, the specific gravity of the blood plasma, however, remaining unchanged. These results indicate that the Shiga toxin produces typical shocklike hemoconcentration.

A compensating vasoconstriction in the duodenum was demonstrated by killing dogs seven to eleven minutes after the toxin injection. The dogs were killed by an intravenous injection of solution of tormaldehyde. The digestive tracts of these and an equal number of control animals were opened and immersed in an acidified saturated solution of amphetramine containing a small amount of hydrogen peroxide. The amphetramine solution produces a deep blue on contact with the red blood cells in the intestinal mucosa. The toxic dogs showed focal blue staining areas of the duodenal mucosa, as contrasted with the diffuse staining in the control animals. Penner interprets this as evidence of focal mucosal vasoconstrictions compensating for the evidently decreased circulating blood volume. Somewhat similar mucosal vasoconstrictions were noted in rabbits, in which animals, however, the vascular reaction is largely confined to the cecum.

To test the direct action of Shiga toxin on the mucosa, repeated doses of the toxin were introduced into thirty-six midjejunal intestinal loops. Practically no direct toxic effect was noted in these nonduodenal loops. Absorption through the jejunal mucosa, however, was deduced from the appearance of typical duodenal lesions in the same dogs. From this and other evidence Penner concludes that the pathologic alterations in the intestinal tract following jejunal absorption or intravenous injection of Shiga toxin are the anatomic end results of a pronounced and prolonged homeostatic duodenal vasoconstriction.

Thus far the investigators have not attempted to apply this incipient theory to the treatment of human dysentery. Evidently, however, their systemic theory of the nature of the colonic lesion suggests numerous hitherto untried methods of prophylaxis or therapy.

Current Comment

HEALTH CONDITIONS IN A NEW YORK CITY DISTRICT

A recent review of the health and the social and economic conditions in a small area in East Harlem, New York City,¹ revealed 3,653 instances of chronic disease among 2,863 of 9,119 persons. Nearly 1 out of every 3 persons suffered from one or more specific types of chronic ailment. Some 539 cases, or 5.9 per cent of the studied population, had venereal diseases. The highest incidence, 6.9 per cent, was found among the Puerto Ricans, who constituted 46 per cent of the studied group; the incidence among the Negro and white groups, 3.7 and 1.7 per cent of the population respectively, was 6.04 and 2.9 per cent respectively. Some form of cardiovascular disease was found in 5.65 per cent of the surveyed population. Tuberculosis ranked third in prevalence of chronic diseases in the studied population. Indeed, the death rate from tuberculosis of the area in 1939 was three times as high as that for New York City as a whole. The population makeup of the area did not entirely explain the high degree of prevalence of tuberculosis. The high rate of 5.9 per cent was expected for the Puerto Ricans, but the rate of 3.3 per cent for white persons was significantly higher than that estimated for the entire New York City or United States populations. Of the 361 persons who had tuberculous infection more than one fourth were children under 15 years of age. The incidence of nervous and mental diseases was somewhat higher in this study than that found in the national health survey; the incidence of cancer and other tumors, while not numerous enough to be statistically significant, did not appear to differ from that in the general population; diabetes was reported in only 53 cases and was not statistically significant. In the area surveyed the Puerto Ricans formed the largest as well as the youngest population group. Nevertheless the total incidence

of chronic disease was as great among them as among the Negroes or the white persons. They accounted for almost half of all those suffering from chronic disease and were responsible for a disproportionate percentage of the cases of tuberculosis (68.1 per cent) and venereal diseases (53.8 per cent). The social and economic conditions in this population seemed materially worse in all respects than the averages of the population which surrounds it both in the city and in the nation as a whole. This type of study is more valuable in revealing practical opportunities for introducing improvement than are most general surveys which do not clearly delimit the nature of the problems or the interacting social, economic and health factors.

PHYSIOLOGY OF DELAYED PARACHUTE JUMPS

Certain hitherto have become apparent in the available knowledge concerning the physiologic effects of free fall through the air. Additional information on this subject is now supplied by the report of an important investigation of the subject by Carlson, Ivy and their colleagues.¹ Their observations, all made on Mr. Arthur H. Starnes, an experienced parachute jumper, involved careful recordings of physiologic and psychologic elements involved in free falls. Various specially devised or adapted instruments were employed including a pneumograph-barograph, a voice transmitter, a motion picture camera and an altimeter. Six free falls were studied. These occurred through distances which ranged from 8,400 to 29,300 feet. The rate of free fall varied from an average of 112 to 158 miles an hour in the case of the lower altitudes to 171 miles an hour in the free fall from 31,400 feet above sea level. The rate of fall, they say, depends on the weight of the falling body in relation to the air resistance, which in turn depends on the density of the air and the position of the body. The maximum average rate calculated for 4.6 second intervals was about 229 miles an hour. The heart rate during the free fall from 31,400 feet was within the normal range; this was determined by broadcast to the ground by special apparatus which picked up cardiac potentials from chest leads. The blood pressure is not significantly influenced, according to the evidence based on Mr. Starnes's reactions during fall and on studies carried out during rapid recompression in an altitude chamber. A transient "blackout," or loss of consciousness, may occur when the rate of fall is suddenly checked by the opening of the parachute. Respiration is irregular, varying from three to fourteen respirations during the various free falls. Auditory acuity is definitely diminished during free falls, visual acuity, however, is not impaired when goggles are worn. The position of the body during a free fall is not fixed, and the body tends to wobble, twist and spin. However, the human body can be kept nearly vertical, with head up and without vertical spinning, by use of an accessory "antispin" parachute. This position has certain physiologic advantages and reduces

¹ Health, Social and Economic Conditions in Health Area 20, East Harlem Health District. Department of Health, New York City, prepared by Special Committee on Health Area 20 of the East Harlem District Health Committee, 158 East 115th Street, New York, 1942.

¹ Carlson, A. J., Ivy, A. C., Krasno, L. R. and Andrews, A. H. The Physiology of Free Fall Through the Air. Delayed Parachute Jump. Quart. Bull. Northwestern Univ. Med. School, 16: 254 (Winter Quarter) 1942.

one of the hazards of parachute jumping, namely twisting and fouling of the shroud lines of a parachute. Convincing evidence was obtained that, at least in the experienced person, mental reactions are clear and rapid during an extended free fall through the air. Of the various positions of the body in falling the rapid, flat spin, according to Mr. Starnes, is the most uncomfortable and the most difficult to break by voluntary movements. Falling feet down at an angle of about 75 degrees, so that one can view the earth, is the most comfortable. The principal conclusion agrees with that previously expressed by Lieut. Col. H. G. Armstrong,² namely that delayed parachute jumps are an entirely practical means of avoiding certain highly hazardous aerial situations, such as the danger of the parachutist being shot down by an unscrupulous enemy in a plane.

THE WAR SURGEON

There is no substitute for the artistry and technique of a competent surgeon. Techniques change. New drugs and new operative procedures may greatly improve the results of surgery but the most important factor in the treatment of war wounds, as was said by an anonymous writer in World War I, is the good surgeon. In *War Medicine*, published by the American Red Cross Society in France for the medical officers of the American Expeditionary Force, appeared a statement, unsigned but believed to have been written by J. M. T. Finney in 1917, which emphasizes the fact that the surgeon himself is the most important factor in surgical care.

"By sound surgery we mean the assumption of complete inclusive responsibility for every item that enters into the result, the consideration of the wound as well as the patient, the development of an ability to read the wound as well as the man aright. It means quick, innocuous, timely intervention, it means seeing clearly the tomorrow of the wound, it means no intervention unless there is to be a net gain, it means a sharp knife, a good anesthetic, a painless innocuous dressing, it means as much respect for the tissues of the anesthetized man as for the unanesthetized man, it means a training in judgment that unerringly tells when to cut, how far to cut, when to quit cutting. It plays all the defenses and reparative forces of the patient. Good surgery is the exponent of no single method. It recognizes the anatomical and environmental situation in which chemical and physical agencies are useful. Good surgery exploits physiologic rest and fluids and sleep, gives little pain. Good surgery evokes confidence, and confidence begets rest, and rest begets restoration. Good surgery, then, makes use of antiseptics and physical forces, just as it uses incisions, counterdrainage, revisions, skin grafting, blood transfusion. Good surgery does not substitute an easy formula for its principles, above all, it always is dissatisfied with its work and is open to suggestion.

"What can the good surgeon accomplish in war with wounds, with good opportunity but no antiseptics? Without antiseptics he can close by primary union a higher percentage of contaminated wounds than he can with antiseptics, he is able to remove damaged tissue with such accuracy that the natural defenses of the revised wound become its best antiseptic, he closes penetrated knee joints more securely without than with antiseptics, he closes penetrated skulls without, better than with, antiseptics, he operates on perforated intestines more successfully without than with antiseptics, he clears up foul and infected superficial wounds as well without as with antiseptics, he meets gas gangrene with the timely use of the knife as well without as with chemical agents. He closes healthy superficial wounds with early suture tied lightly, healthy wounds that cannot be closed by suture he closes by skin grafting, both as a healing and as a bactericidal policy, he closes fecal and urinary fistulae without antiseptics.

In the rush of a great battle, he would incise for drainage, and in addition he would make 'physiologic incisions' to avoid tension that is sure to follow the next day from the inevitable infection.
